VHPI Standard Specification

Draft 4.7

Deleted: 6

1		
2	VHPI STANDARD SPECIFICATION.....	1
3	DRAFT 4.6	1
4	VHDL PROCEDURAL INTERFACE.....	13
5	1. OVERVIEW	13
6	1.1 SCOPE AND PURPOSE OF THE VHDL PROCEDURAL INTERFACE	13
7	1.1.1 VHDL Procedural interface requirements and guidelines	13
8	THE PLI SHOULD BE ANSI C COMPATIBLE.	14
9	THE WORKING GROUP WILL EVALUATE IF THE PLI INTERFACE SHOULD REQUIRE	
10	VITAL SPECIFIC INFORMATION.	15
11	TBD.....	15
12	GUIDELINES.....	15
13	THERE ARE 7 GUIDELINES.....	15
14	1.1.2 VHPI capability sets and conformance	15
15	1.2 INTERFACE NAMING CONVENTIONS	16
16	1.3 PROCEDURAL INTERFACE OVERVIEW.....	17
17	2. VHPI HANDLES.....	17
18	2.1 OBJECTS AND HANDLES.....	17
19	2.2 HANDLE MANAGEMENT FUNCTIONS	18
20	2.2.1 Handle creation.....	18
21	2.2.2 Handle release.....	18
22	2.2.3 Handle comparison	18
23	2.3 LIFETIME OF OBJECTS AND HANDLES	18
24	2.3.1 Object lifetime.....	18
25	2.3.2 Handle lifetime	19
26	2.3.3 Invalid handles	19
27	2.3.4 Referential integrity.....	19
28	2.4 META HANDLES.....	19
29	2.4.1 Iterator class.....	20
30	2.4.2 Collection class	20
31	3. INTERFACE FUNCTION OVERVIEW.....	22
32	3.1 INFORMATION ACCESS ROUTINES	22
33	3.1.1 Single relationship traversal function	22
34	EXAMPLE 1: UNNAMED RELATIONSHIPS.....	22
35	EXAMPLE 2: TAGGED RELATIONSHIPS.....	23
36	3.1.2 Iteration functions and vypi_handle_by_index	24
37	EXAMPLE:.....	24
38	PLEASE REFER TO THE SCOPE CLASS DIAGRAM.....	24
39	3.2 SIMPLE PROPERTY ACCESS FUNCTIONS	24
40	3.2.1 Integer or boolean properties.....	24
41	PROCEDURAL INTERFACE REFERENCES:	25
42	ENUMERATION TYPE FOR THE INTEGER OR BOOLEAN PROPERTIES IS	
43	VHPIINTPROPERTYT.	25

1	ERRORS:	25
2	3.2.2 <i>String properties</i>	25
3	26
4	PROCEDURAL INTERFACE REFERENCES:	26
5	ENUMERATION TYPE FOR THE STRING PROPERTIES IS VHPISTRPROPERTYT.	27
6	SEE ANNEX B FOR DESCRIPTION OF EACH STRING PROPERTY.	27
7	ERRORS:	27
8	3.2.3 <i>Real properties</i>	27
9	PROCEDURAL INTERFACE REFERENCES:	27
10	ENUMERATION TYPE FOR THE REAL PROPERTIES IS VHPIREALPROPERTYT	27
11	3.2.4 <i>Physical properties</i>	27
12	PROCEDURAL INTERFACE REFERENCES:	27
13	ENUMERATION TYPE FOR THE PHYSICAL PROPERTIES IS VHPIPHYSPROPERTYT.	27
14	ERRORS:	27
15	3.3 LOOK UP BY NAME.....	27
16	3.4 VALUE MANIPULATION FUNCTIONS	28
17	3.4.1 <i>Value access function</i>	28
18	3.4.2 <i>Value formatting function</i>	28
19	3.4.3 <i>Value modification functions</i>	28
20	3.5 FOREIGN MODEL SUPPORT	28
21	3.6 CALLBACKS.....	28
22	3.6.1 <i>Functions for registration, removing, disabling, enabling callbacks</i>	28
23	3.7 UTILITIES AND MISCELLANEOUS FUNCTIONS	29
24	3.7.1 <i>Error checking</i>	29
25	3.7.2 <i>Printing to stdout and log files</i>	29
26	3.7.3 <i>Optional Save/Restart Support</i>	29
27	3.7.4 <i>Miscellaneous Functions</i>	29
28	4. THE VHDL PLI INFORMATION MODEL	30
29	4.1 FORMAL NOTATION	30
30	UML NOTATION QUICK REFERENCE	30
31	A CLASS	30
32	A MEMBER CLASS	30
33	ASSOCIATIONS	30
34	4.2 CLASSES OVERVIEW	31
35	(1) THE BASE CLASS IS THE TOP OF THE CLASS HIEARCHY	33
36	(2) THE NULL CLASS DENOTES THE VHDL ELABORATED OR UNINSTANTIATED DESIGN.	
37	33
38	ATTRSPEC	34
39	STACKFRAME	34
40	CONDWAVEFORM	35
41	ASSOCELEM	35

1	4.3	STANDARD HIERARCHY PACKAGE (HIERARCHY CAPABILITY SET)	38	
2	4.3.1	The region inheritance class diagram	38	
3	4.3.2	The port class diagram	39	
4	4.3.3	The generics class diagram	40	
5	4.3.4	The signals class diagram	41	
6	4.3.5	The variable class diagram	42	
7	4.3.6	The constant class diagram	43	
8	4.3.7	The structural class diagram	44	
9	4.4	STANDARD UNINSTANTIATED PACKAGE (POST ANALYSIS CAPABILITY SET)	45	
10	4.4.1	The design unit class diagram	45	
11	4.4.2	The lexical scope diagram	45	
12	4.4.3	The configuration declaration class diagram	46	
13	4.5	THE STANDARD DECLARATION PACKAGE (HIERARCHY AND STATIC CAPABILITY SETS)	48	
14	4.5.1	The declaration class inheritance diagram	48	
15	4.5.2	The object class diagram	49	
16	4.5.3	The composite object class diagram	52	
17	4.5.4	The alias declaration diagram	53	
18	4.5.5	The group declaration diagram	55	
19	4.5.6	The file inheritance diagram	55	
20	4.6	THE STANDARD TYPE PACKAGE (STATIC ACCESS CAPABILITY SET)	56	
21	4.6.1	The type and subtype class diagram	56	
22	4.6.2	The type inheritance class diagram	58	
23	4.6.3	The scalar type class diagram	60	
24	4.6.4	The constraint class diagram	61	
25	4.7	THE STANDARD SPECIFICATION PACKAGE (STATIC ACCESS CAPABILITY SET)	63	
26	4.7.1	The attribute declaration and specification class diagram	63	
27	4.7.2	The attribute specification associations	64	
28	4.7.3	The disconnection specification class diagram	65	
29	4.7.4	The specifications diagram	65	
30	4.8	THE STANDARD SUBPROGRAM PACKAGE (STATIC ACCESS AND DYNAMIC ELAB CAPABILITY SETS)	66	
31	4.8.1	The subprogram declaration class diagram	66	
32	4.8.2	The subprogram call class diagram	67	
33	4.9	THE STANDARD STATEMENT PACKAGE (STATIC ACCESS CAPABILITY SET)	69	
34	4.9.1	The concurrent statement class diagram	69	
35	4.9.2	The structural statement class diagram	70	
36	4.9.3	The generate statement class diagram	71	
37	4.9.4	The sequential statement inheritance class diagram	73	
38	4.9.5	The sequential case, if, wait and return statement class diagram	75	
39	4.9.6	The sequential loop, exit and next statement diagram	76	
40	4.9.7	The sequential variable assignment, assert and report statement diagram	76	
41	4.9.8	The signal assignment statement class diagram	78	
42	4.10	THE STANDARD EXPRESSION PACKAGE	79	
43	4.10.1	The expression inheritance diagram	79	
44	4.10.2	The simple name class diagram	80	
45	4.10.3	The attribute class diagram	81	
46	4.10.4	The type conversion, aggregate class diagram	82	
47	4.10.5	The name access class diagram	82	
48	4.10.6	The literal class diagram	84	
49	4.11	THE STANDARD CONNECTIVITY PACKAGE	85	
50	4.11.1	The driver class diagram	85	
51	4.11.2	The contributor inheritance diagram	86	
52	4.11.3	The basic signal class diagram	86	
53	4.11.4	The connectivity diagram	88	
54	4.11.5	The loads class diagram	89	
55	4.12	THE STANDARD CALLBACK PACKAGE	90

44		NOTES:.....	130	Deleted: 113
45		EXAMPLE:.....	130	Deleted: 113
46		“VHPIDIRECT <LIBRARY_NAME> <EXECF_NAME>”.....	132	Deleted: 115

1	WHERE <LIBRARY_NAME> AND <EXECF_NAME> CAN BE THE NULL TOKENS.....	132	Deleted: 115
2	THE FOREIGN ATTRIBUTE STRING MUST BE LOCALLY STATIC AND MUST BE A		
3	STRING THAT STARTS WITH THE VHPIDIRECT KEYWORD.	132	Deleted: 115
4	7.3 REGISTRATION	132	Deleted: 115
5	7.3.1 Delivery and packaging of libraries of foreign VHPI models or applications.....	132	Deleted: 115
6	FOR A LIBRARY OF FOREIGN MODELS:	133	Deleted: 116
7	COMMENTS MAY BE INCLUDED IN THE FILE, EACH COMMENT LINE MUST START BY		
8	A "--" CHARACTER. THE LIBRARY, MODEL, APPLICATION AND FUNCTION NAMES		
9	MUST BE FORMED WITH GRAPHICAL CHARACTERS AND CAN BE EXTENDED		
10	IDENTIFIERS. THE ELABORATION, EXECUTION AND BOOTSTRAP FUNCTION NAMES		
11	SHOULD BE THE C SOURCE FUNCTION NAMES. ONE OR MORE SPACES CAN OCCUR		
12	BETWEEN NAMES. THE NULL TOKEN SHOULD BE ENTERED IN THE PLACE OF A C		
13	FUNCTION NAME IF NO FUNCTION NAME IS PROVIDED. IN THE CASE OF A NULL		
14	EXECUTION_FCTN_NAME FOR A FOREIGN SUBPROGRAM, THE NAME OF THE		
15	FUNCTION DEFAULTS TO THE NAME OF THE MODEL NAME.....	133	Deleted: 116
16	IF SEVERAL BOOTSTRAP FUNCTIONS ARE ASSOCIATED WITH A LIBRARY, AN ENTRY		
17	FOR EACH BOOTSTRAP FUNCTION MUST BE IN THE REGISTRY FILE.	133	Deleted: 116
18	EXAMPLE :	133	Deleted: 116
19	REGISTRY_FILE CONTENTS EXAMPLE	133	Deleted: 116
20	7.3.2 Registration functions for foreign models and applications.....	133	Deleted: 116

23	7.3.3 Registration and binding errors	135	Deleted: 118
24	7.3.4 Restrictions	135	Deleted: 118
25	7.4 ELABORATION OF FOREIGN MODELS	135	Deleted: 118
26	7.4.1 Elaboration of foreign architectures	135	Deleted: 118
27	7.4.2 Elaboration function.....	135	Deleted: 118
28	7.4.3 Elaboration of foreign subprograms	135	Deleted: 118
29	NOTE: LRM MODIFICATIONS NEEDED PAGES 156, 157, 163.....	135	Deleted: 118
30	A FOREIGN FUNCTION CAN BE CALLED DURING ELABORATION PHASE TO INITIALIZE		
31	DECLARED ITEMS. THE EXECF FUNCTION IS USED TO PROVIDE THE INITIAL VALUE		
32	OF THE DECLARED OBJECT.....	136	Deleted: 119
33	NOTE: LRM MODIFICATION NEEDED FOR ELABORATION OF DECLARED OBJECTS		
34	INVOLVING FOREIGN FUNCTIONS.	136	Deleted: 119
35	7.5 SIMULATION RUN TIME EXECUTION	136	Deleted: 119
36	7.5.1 Simulation of foreign architectures	136	Deleted: 119
37	7.5.2 Initialization function	136	Deleted: 119
38	7.5.3 Simulation of foreign subprograms	136	Deleted: 119
39	WHEN A FOREIGN SUBPROGRAM CALL IS ENCOUNTERED DURING VHDL EXECUTION,		
40	THE SIMULATION EXECUTION FUNCTION IS CALLED: THE CONTROL FLOW OF A		
41	FOREIGN SUBPROGRAM CALL IS DETERMINED BY THE VHDL SIMULATION		
42	SEMANTICS.	136	Deleted: 119
43	7.5.4 Execution function	136	Deleted: 119
44	7.5.5 Restrictions and errors	140	Deleted: 123
45	PROCEDURAL INTERFACE REFERENCES:	140	Deleted: 123

1	7.6	CONTEXT PASSING MECHANISM.....	140	Deleted: 123
2	7.6.1	Architecture instance.....	140	Deleted: 123
3	7.6.2	Subprogram Calls.....	141	Deleted: 124
4		VHPI_PUT_VALUE() METHOD CAN BE APPLIED TO FORMAL PARAMETERS OF MODE		
5		OUT OR INOUT; IT WILL UPDATE THE VALUE OR SCHEDULE A ZERO DELAY		
6		TRANSACTION ON THE VHDL FORMAL PARAMETER DEPENDING ON THE FLAGS AND		
7		CLASS OF THE PARAMETER. VHPI_SCHEDULE_TRANSACTION CAN BE APPLIED TO A		
8		FORMAL SIGNAL PARAMETER OF MODE OUT OR INOUT.....	142	Deleted: 125
9		NOTE: PAGE 20 AND 21 OF THE LRM HAS TO BE UPDATED WITH FOREIGN		
10		SUBPROGRAMS.....	142	Deleted: 125
11		PROCEDURAL INTERFACE REFERENCES:	142	Deleted: 125
12	7.7	SAVE, RESTART AND RESET	142	Deleted: 125
13	7.7.1	Saving foreign models	142	Deleted: 125
14		SEE EXAMPLE IN THE PROCEDURAL INTERFACE REFERENCE FOR VHPI_PUT_DATA().		
15		143	Deleted: 126
16	7.7.2	Restarting foreign models.....	143	Deleted: 126
17		SEE EXAMPLE IN THE PROCEDURAL INTERFACE REFERENCE FOR VHPI_GET_DATA().		
18		144	Deleted: 127
19	7.7.3	Reset of foreign models state	144	Deleted: 127
20	2.	THE SIMULATOR REMOVES ALL SCHEDULED TRANSACTIONS AND ALL USER		
21		REGISTERED CALLBACKS WITH THE REQUIRED EXCEPTION OF VHPICBENDOFRESET		
22		CALLBACKS.	145	Deleted: 128
23	3.	RESET THE VHDL SIMULATION STATE TO THE BEGINNING OF INITIALIZATION,		
24		TC = 0 NS, READY TO COMMENCE EXECUTION OF INITILIZATION PHASE 1.0.1 IN THE		
25		ANNOTATED SIMULATION CYCLE.	145	Deleted: 128
26	4.	EXECUTE ALL USER REGISTERED VHPICBENDOFRESET CALLBACKS,		
27		OPPORTUNITY FOR A CLIENT APPLICATION TO REGISTER CALLBACKS.....	145	Deleted: 128
28	5.	INITIALIZATION PHASE STARTS AT 1.0.1 IN THE ANNOTATED SIMULATION CYCLE.		
29		145.		Deleted: 128
30	7.7.4	Save, restart and reset of VHPI applications	145	Deleted: 129
31	7.7.5	Getting the simulation save and restart location.....	145	Deleted: 129

VHDL Procedural Interface

1. Overview

1.1 Scope and Purpose of the VHDL Procedural Interface

Design a standard procedural interface for VHDL. The outcome should be a specification that is implementor independent and which can be used on any VHDL compliant tool. Supports the current standard version of VHDL and any past versions as needed. The interface should define the semantics for a mixed language design and define the elaboration/instantiation and access methodology during runtime of foreign models. The interface provides a mechanism to interact, control and communicate with a VHDL compliant tool. The interface is an ANSI C procedural interface, which guarantees C source code portability across all tools compliant with the interface. Even though the interface defines symbolic constant values and C data structures which are a step towards binary portability, C object code binary portability across same hardware/OS is not guaranteed. Vendors or application writers should document application binary interface issues which would affect their integration or would not be compatible with their PLI implementation. The interface provides a VHPI header file which defines the required VHPI access. The compliance with the standard requires a vendor to preserve the VHPI standard file. This VHPI interface provides extensibility for a vendor VHPI implementation

1.1.1 VHDL Procedural interface requirements and guidelines

There are 10 requirements:

#1 functionality:

The procedural interface functionality can be divided in 2 parts: the **core** functions and the **utility** functions.

core: The interface should provide core functionality that enables the development of applications such as:

- design traversals, netlisters,
- connectivity extractors,
- co-simulation, backplane interfaces,
- behavioral models,
- debugging environments,
- simulation testbench and verification,
- VHDL code profilers and coverage tools,
- VHDL decompilers,
- delay calculators.

These various types of applications require different capabilities to be supported by the VHDL procedural interface; they can be classified in 4 categories:

1. access to static VHDL design data
2. access and modification of specific VHDL objects
3. simulation interaction and control
4. foreign model instantiation and intercommunication mechanism with VHDL design

Class 1 functionality should provide access to the elaborated model. Complete (with the exception of protected data see requirement # 2) behavioral and structural access is highly desirable for back end tools such as synthesis tools, delay calculators design verification tools. If the procedural interface provides complete access to the static design data it should be possible to decompile a design that was analyzed and regenerate an equivalent VHDL description. Delay calculation and back annotation through VHPI is considered as lower priority and is not addressed in this first version of the standard. Read access to

generic values which specify delays are however possible with this version of the standard. There are several reasons behind pushing out providing the delay calculation and annotation capabilities:

1. No existing C interface has this capability,
2. SDF back annotation or proprietary delay calculation or back annotation tools have been used for VHDL designs.
3. A group under the DASC is working on a new standard for delay calculation and annotation (DPC) and will fulfill this need. <http://www.vhdl.org/dpc>

Class 3 functionality should provide the **ability to change values** of VHDL objects during elaboration or simulation. Valid objects that can be modified will be specified.

Class 3 functionality should provide **simulation interaction** such as the ability to schedule events and transactions, query the simulation state and time queue and interrupt the simulation engine at defined times or for various reasons.

Class 4 functionality should provide a mechanism to **elaborate foreign models** with VHDL models. This mechanism should specify how one can use a foreign model in a VHDL model and how the foreign model should access and propagate values to and from the VHDL model.

The interface should provide support for **event-driven** as well as for **alternative algorithms for simulation**.

Utilities: Core utility functions such as printing, displaying and comparison functions are necessary. The interface should provide an error handling mechanism, strong error detection and a set of known error codes that the user can reference. All of the PLI functions should give an indication of how and why they fail if they fail.

#2 restricted access to protected data:

VHDL does not define a mechanism to specify protected source code. The access to protected models should be restricted to the information that can be found in a model vendor library and what is necessary for interfacing the library cells in the VHDL design.

#3 Memory management:

The procedural interface should provide functionality to allow the application to manage the lifetime of the memory allocated by the PLI.

#4 Hide internal data representation:

The application cannot make assumptions about the underlying data implementation. It must use the defined mechanisms for data manipulation.

#5 Portability:

The PLI should be ANSI C compatible.

The mechanism that the PLI interface provides for integrating PLI applications or models should be easily portable to major platforms, i.e. UNIX or NT.

#6 Allowing multiple concurrent PLI applications:

The PLI should support simultaneous use and parallel read-only access to the same data. Note: Parallel modification (write access) to the same data may be indeterministic and may be implementation dependant. The design solution may determine the outcome of this issue.

#7 VITAL:

The working group will evaluate if the PLI interface should require VITAL specific information.

#8 Saving/Restoring:

The PLI should support a mechanism to save and restore PLI application state; after a restore operation, the VHDL compliant tool should be able to continue.

#9 Resetting a simulation state:

For simulation tools, the PLI should provide a mechanism to reset to time 0 which is the time just after simulation initialization.

#10 evaluate co-simulation requirements:

TBD

Guidelines

There are 7 guidelines.

#1 Do not preclude mixed signal VHDL.

#2 Provide for smooth crossing of VHDL/Verilog domains

#3 performance

The interface should provide fast access to data. In particular, when the interface functions are used for communicating with a simulator, where speed is the most important thing.

#4 capacity

The procedural interface should be able to handle large designs and should manage memory internally.

#5 versioning

A mechanism should be provided to determine adequate version information for the PLI interface, the simulator and relevant models.

#6 Function, data type names should be intuitive and seem natural to somebody who knows VHDL.

#7 The working group will evaluate relevant existing interfaces with the possibility of leveraging prior work.

1.1.2 VHPI capability sets and conformance

The standard define clusters of VHPI capability, a vendor may claim conformance to several VHPI capabilities. The claim of conformance to a VHPI capability requires that a vendor provides a compliant implementation to all the methods, properties and functions referred by that capability.

All vhpi functions defined by the standard should, if not implemented return an unimplemented error message.

An integer property vhpiCapabilitiesP can be queried from the tool class to check the vendor supported VHPI capabilities. There is an enumeration constant defined for every capability.

A tool which supports a given phase shall support the vhpiStartOf phase name and vhpiEndOf phase name that phase.

VHPI defines ten capabilities:

- . the hierarchy capability:** access to elaborated regions, design units, object declarations, types and subtypes. `vhpi_handle_by_name`, `vhpi_get_value` of declared objects. This capability enumeration constant is `vhpiProvidesHierarchy`.
- . the VHDL static access capability:** complete post elaboration static access including statements, expressions, access to values of declared items after elaboration (`vhpi_get_value`). The capability enumeration constant is `vhpiProvidesStaticAccess`. It is a superset of the hierarchy set. It requires the hierarchy capability.
- . the connectivity capability:** access to VHDL drivers and contributors, port connections. It also requires the hierarchy capability. The capability enumeration constant is `vhpiProvidesConnectivity`.
- . the post analysis capability** (uninstantiated VHDL access) allows traversal of statements, expressions, design units, etc... This capability set provides VHPI access after VHDL analysis and traversal of specific relationships from the instantiated model to the uninstantiated model (section 5.8). Also provides `vhpi_get_value` of objects which are initialized to locally static expressions and `vhpi_handle_by_name` in the uninstantiated domain. The capability enumeration constant is `vhpiProvidesPostAnalysis`.
- . the basic foreign models capability:** ability to create foreign architectures and subprograms (`vhpi_register_foreignf`, `vhpi_get_foreignf_info`), foreign architecture and subprogram information model access, specific foreign model callbacks, general callbacks, `vhpi_get_value` and `vhpi_put_value`. The capability enumeration constant is `vhpiProvidesForeignModel`. It also requires the hierarchy capability.
- . the advanced foreign models capability:** creation of foreign drivers and processes, scheduling of transactions to foreign drivers. The capability enumeration constant is `vhpiProvidesAdvancedForeignModel`. It requires the basic foreign model capability.
- . the save/restart capability:** save and restart of foreign models and applications, `vhpi_put_data`, `vhpi_get_data`, callbacks for save and restart, `vhpiIdP`, `vhpiSaveRestartLocationP`. The capability enumeration constant is `vhpiProvidesSaveRestart`.
- . the reset capability:** reset to time zero for foreign models and applications, callbacks for reset. The capability enumeration constant is `vhpiProvidesReset`.
- . the debug and runtime simulation capability:** `vhpi_control`, `vhpi_get_time`, `vhpi_get_next_time`, `vhpi_handle_by_name`, access to the supported static information model, including at a minimum accessing objects, reading and modification of object values, scheduling transactions to drivers, registering object value change callbacks as well as time and action callbacks. The capability enumeration constant is `vhpiProvidesDebugRuntime`.
- . the dynamically elaborated capability:** access to dynamically elaborated objects (VHDL subprograms, for loops). The compliance set enumeration constant is `vhpiProvidesDynamicElab`. It requires the debug and runtime simulation capability.

1.2 Interface Naming Conventions

The VHDL Procedural Interface is denoted by the short name of **VHPI** which stands for the **VHDL Procedural Interface**.

1. All standard functions, classes, types, relationship tag names, enumeration constants defined by the interface starts by the prefix **“vhpi”**.

2. The VHPI standard function names are lower case characters and have an underscore between each word; all other names (classes, relationship tags, enumeration constant identifiers will have no underscore and each word after the VHPI prefix will start by a upper case letter followed by lower case letters for the remaining of the word.
3. All defined VHPI types will end in a capital **T**.
4. One to many relationship tag names have an s (lower case) at the end.
5. VHPI uses some short name conventions: for example decl for declaration, stmt for statement, conc for concurrent, seq for sequential, subp for subprogram...
6. The VHPI class kind names end by the letter **K**.
7. The VHPI property names end by the letter **P**.

1.3 Procedural Interface Overview

The VHDL procedural interface is based on:

- the definition of a VHDL **information model** that represents the static and dynamic VHDL data that is accessible by the procedural interface,
- a **small set of functions** that operate on this model to access data, query about some particular piece of information, modify data, interact with the tool that supports the model or provide utilities such as for printing or checking errors for example...

The VHDL PLI information model is based on an *object-oriented* representation of the VHDL *post-elaborated* and *simulation data*. It partitions the VHDL data into *VHPI classes* that are connected by *relationships*. We use the same terminology that is used in object-oriented software design. A VHPI class is a set of VHPI data types which share the same functional *methods* and *properties*. An instance of a class is called an *object*. A class can have zero or more *member* classes. Member classes are said to be derived from the class they belong to (the parent class). Member classes *inherit* the methods and properties of their parent classes. The relations between a class and the rest of the information model are defined by the information model and methods are available to traverse the external class links. There are basically three classes of relationships: the *one-to-one* relationship, the *one-to-many* relationship and the *many-to-many* relationship.

The first relationship describes the fact that given an object of a certain class, and given a destination class type, at most one object of the destination class can be obtained. The second relationship describes the fact that, given an object of a certain class, and a destination class type, there can be many reachable objects of that target class. The third type of relationship specifies the fact that, given two or more objects of the same or different class type, and given a destination class type, more than one object of that target class can be obtained. VHPI functions are provided to traverse these relationships. These three classes of relations are sufficient to describe the navigation throughout the VHPI information model. At present the VHPI information model only uses the first and second classes of relationships. A class can also have *properties* that generally describe inherent characteristics or attributes of that class. Property values can be queried with some predefined VHPI functions. Other functions are provided to *get* or *modify* VHDL values; these functions are only available from some classes of objects. Interaction between the VHPI interface and the tool is achieved via *callbacks*. Finally, *utility* functions are provided for printing, checking errors for example. In summary, the procedural interface contains about thirty functions, from which less than ten are used for accessing the complete VHDL information model.

2. VHPI Handles

2.1 Objects and handles

Object definition: The VHPI information model represents VHDL static and runtime data. In the VHPI information model, there are static and dynamic objects represented as classes with associated properties and methods.

Handle definition: A handle is a reference to an object of the information model.

The VHPI functions manipulate VHDL data at some abstraction level. The user only gets back *handles* which basically are an abstract representation of some VHDL object such as for example, an instance, a signal or a transaction. A handle is an *opaque* pointer to some VHDL object represented in the information model. The handle identifies some static elaborated and/or dynamic runtime VHDL information, the VHPI interface knows how to relate handles with the object they represent. Users cannot make an assumption about the underlying internal representation of a handle.

The C type of the handle (`vhpiHandleT`) is predefined by the interface (`typedef PLI_UINT32 *vhpiHandleT`). The VHPI interface functions manipulate and create handles. A VHPI handle is used to reference any VHDL object that is defined in the information model that is identifying static or dynamic data. The VHPI interface defines a meta model that describes the mechanisms on how to access information. In the meta model, any handle has one property called *vhpiKindP* that identifies the class of which the VHPI handle is an instance. The class defines the type of VHDL information the handle points to. For example, if a VHPI handle is a handle to a variable declaration, the kind property will return the integer constant corresponding to the variable declaration class (`#define vhpiVarDeclK <number>`). The interface predefines an integer kind for each leaf class of the information model. Depending on the handle class, some relations (methods), properties (attributes) are available; these relations and properties are described by the VHPI information model. VHPI interface functions only apply to the leaf classes.

2.2 Handle management functions

In this section, we describe how handles to objects denoted by the information model are allocated and freed.

2.2.1 Handle creation

Handles are created by the VHPI interface navigation and creation functions. An interface implementation may choose to share handles between various applications and to return the same handle each time the same object is accessed. Handle creation can be optional for certain classes of objects such as callbacks where the user is given the choice to request explicitly the creation of a handle. All access navigation functions such as *vhpi_iterator()*, *vhpi_scan()*, *vhpi_handle()*, *vhpi_handle_by_name()* and *vhpi_handle_by_index()*, (refer to chapter 3) create and return handles. Handles are owned by the VHPI client application.

2.2.2 Handle release

All handles need to be explicitly released by the VHPI user. A function (*vhpi_release_handle()*) is provided to request the release of a handle. If a handle is shared between VHPI applications, the release of the handle may not be effective until all client applications have requested the handle release. After a handle is released, **no** reference should be made to that handle. The user cannot assume that the handle still exists neither that it refers to the same object. It is recommended that VHPI users release handles when they are not needed. An iterator is automatically released by the VHPI interface at the end of the iteration.

2.2.3 Handle comparison

Two different handles may identify the same VHPI object. The interface provides a function to compare two handles (*vhpi_compare_handles()*). This function will return true if the handles refer to the same object, false otherwise.

2.3 Lifetime of objects and handles

2.3.1 Object lifetime

A static object comes into existence at a particular point in time in the tool's execution and lives until the tool exits. When an object comes into existence, it is possible to obtain a handle to the object. For example, a component instance in the design hierarchy is a static object that comes into existence sometime during elaboration.

1 A dynamic object comes into existence and may cease to exist sometime later. They exist for as long they
2 are required or until they are removed. For example, subprogram's formal parameters are dynamically
3 elaborated when the subprogram is called and cease to exist when the subprogram completes and returns.
4 Transactions on drivers are created with waveforms and may be cancelled by future waveform edits.
5 Callbacks are created and removed by the VHPI user.

6 2.3.2 Handle lifetime

7
8 A handle comes into existence when it is returned to the user. It lives until the user releases it.
9 There are various methods of navigating the VHPI information that create and return handles to the user,
10 e.g., *vhpi_handle*, *vhpi_iterator*, *vhpi_create*. The user releases a handle with *vhpi_release_handle*.
11

12 2.3.3 Invalid handles

13
14 When a handle to an object is obtained, a VHPI client may access through this handle some object
15 properties, access or modify the object runtime value (*vhpi_get_value*, *vhpi_put_value*) or navigate to
16 related objects. If the object is a dynamic object, it may cease to exist. A handle to a dynamic object that
17 no longer exists is called an **invalid** handle. The handle exists, the object doesn't. For any handle, a
18 boolean property is defined to check the validity of that handle (**vhpiIsInvalidP**). An invalid handle may
19 be released by a VHPI application (keeping invalid handles is not very useful).
20
21

22 2.3.4 Referential integrity

23
24 With the above terminology, we can define the concept of referential integrity of handles. In this context, it
25 means that for as long as a handle exists, it is safe to reference it. You may use it in any VHPI function that
26 accepts a handle, and that function will attempt to perform its operation. Regardless whether that attempt is
27 legal in the information model or results in a VHPI runtime error, it will not cause the tool to crash.
28

29 In particular, invalid handles have referential integrity. It may certainly be treated as an error if you
30 reference an invalid handle, depending on the particular type of handle and operation requested.
31 Handles to mature callbacks also have referential integrity. A handle to a mature callback has very little
32 value for a VHPI client: it cannot be re-enabled, and it cannot be discovered via traversal of the information model.
33 It should be deleted by the VHPI server, unless the client (user) has previously obtained a handle to the transaction. If
34 the client has a handle, he has ownership, albeit to something of marginal value. He can query some of its properties
35 and methods it or just waste the memory resource. It follows that, after all such handles are released with
36 *vhpi_release_handle()*, the mature callback should be deleted by the VHPI server. The VHPI server is free to waste
37 resources itself, but the point is, it has ownership of the callback memory.
38

39 If a handle is released regardless how it is released either explicitly by the user or by the tool, it has no
40 longer referential integrity. If you reference a handle after you have released or after an iterator is
41 exhausted, it is an egregious error which can cause the tool to crash. It is similar to referencing freed
42 memory in a C program.
43

44 2.4 Meta handles

45 The information model also defines meta classes. Meta classes do not represent any VHDL object. For
46 example iterator and collection classes (*vhpiIteratorK* and *vhpiAnyCollectionK* kinds) represent
47 respectively iteration lists and ordered collections of objects. Meta handles are subject to the same
48 referential integrity rules as other handles.

2.4.1 Iterator class

Iterator handles are handles defined by the interface to access many objects of the same class type. Iterator handles are used to traverse one-to-many relationships that connect classes. Iterator handles are slightly different from non-meta handles in the sense that they cannot be shared between applications because they hold the state of the current iteration. The *vhpiKindP* of an iterator handle is *vhpiIteratorK*. The iterator class is a sub-class of the base class. A unique iterator handle is created by each call to *vhpi_iterator*. *vhpi_scan* takes an iterator handle and can be used to return a handle to each iteration element. When there is no more element to return, *vhpi_scan* returns a NULL handle. The iterator handle is released automatically by the simulator at the end of the iteration. Reference to the iterator handle after the end of an iteration is erroneous. If the iteration is not exhausted, the user should explicitly release the iterator handle to avoid a memory leak.

Adding elements to an iteration while processing an iterator has unspecified behaviour. For example, while iterating on callbacks, register a new callback, or while iterating over the members of a collection, add a new member has unspecified behaviour.

2.4.2 Collection class

The *vhpiKindP* of a collection handle is either a *vhpiAnyCollectionK* or a specialized collection of objects of the same kind, for example a collection of drivers is *vhpiDriverCollectionK*. The collection class represents a user-defined collection of VHPI objects. The collection contains an arbitrarily sized, ordered set of VHPI objects. The collection may be created at any time, provided, of course the desired object members exist at the time. The purpose of the class is for the organizational convenience of an application or model. Atomic operations are defined on the collection class (see operations). The UML model defines a *oneToMany* method to iterate over the members of the collection (*vhpiMembers*). Iterating on the members of a collection handle only returns the valid handles.

2.4.2.1 Construction of a collection object

A collection object is created with *vhpi_create*. The first call provides a handle to the first object to be added to the collection and returns a handle to the collection object:

```
vhpiHandleT myCollection;  
myCollection = vhpi_create(vhpiAnyCollectionK, NULL, vhpiHandleT  
anyObject);
```

Objects may be added to the collection, one at a time, as follows:

```
myCollection = vhpi_create(vhpiAnyCollectionK, myCollection, vhpiHandleT  
anotherObject);
```

The return value is a handle to the modified collection object or NULL if an error occurred. The original collection object handle shall be passed as the second parameter, the handle to the object to be added to the collection shall be passed as the third parameter. The ordering of the collection set corresponds to the order in which objects are added to it. There is no restriction on when a collection may be created or when objects may be added to an existing collection.

NOTES:

As is the case for all VHPI handles, a handle to a collection does not remain valid across process boundaries that may exist in the architecture of a particular VHPI-compliant tool.

Interleaving addition of elements to the collection while iterating over the members of the collection has unspecified behaviour.

2.4.2.2 Collection Object Lifetime

A collection exists from the time it is created until its handle is released. No navigation VHPI function ever returns collection handles. It is the application/model responsibility to keep a handle to the collection created. It is also its responsibility to release the collection handle when it is no longer needed. Releasing the collection handle does not release the handles the collection contains.

2.4.2.3 Referential Integrity

With respect to a collection of dynamic objects, if a handle to one of the collection members is obtained by iterating over the *vhpiMembers* relationship or accessed via *vhpi_handle_by_index*, it should always return a handle that is safe to reference. It does not matter whether the handle to the object of interest was released, this is a new handle obtained by accessing the collection member object. Moreover, if the collection is a collection of dynamic objects (callbacks for example), it does not matter if the dynamic object was removed or ceased to exist, the reference to it in the collection still exists in the same manner that a callback handle kept by a user can be referenced even after the callback has been removed. Another way of stating the expected behavior is that the referential integrity of a collection transitively includes the referential integrity of a handle to any of its underlying objects.

2.4.2.4 Operations on a collection

There is a powerful generality with a collection that is possible, but it is being used in only one narrow context in the current VHPI specification. VHPI operations are defined on some classes of the information model. A VHPI operation can be applied to a class which possesses that operation, the operation consists in modifying/accessing some of the class internal data. Such operations are for example *vhpi_put_value*, *vhpi_get_value*, *vhpi_schedule_transaction*, *vhpi_register_cb...* Operations operate on an object which reference handle is passed as an argument to the VHPI operation. It is desirable in many contexts to apply the same operation to a set of objects by a series of identical sequential operation calls where the reference handle changes to point to a different object. It would be a very convenient shorthand to allow certain VHPI operations to accept a handle to a collection. Such an operation would appear in the information model as an operation defined on a collection, and you can think of its definition being a "delegated" operation defined on the individual members of the collection. There is no supported use of collections in this manner.

This is also a mechanism that can be used when a series of operations on separate handles must be treated as an atomic operation. A collection of driver handles that represent the sub-element drivers of a composite unresolved signal may be used as the reference handle with *vhpi_schedule_transaction* to schedule a composite transaction. This is the only context that is being proposed for a collection.

Property access or method navigation do not work by delegation: a common property of the elements of a collection cannot be queried on a reference handle of the collection.

2.4.2.5 Error Handling

An operation applied to a collection may have an error associated with one or members of the collection. Such an operation will be recognized as a single error which may be reflected in the return value of function as well as be accessible with *vhpi_check_error*. The correctness of use of an operation on a collection is the transitive correctness of that operation on each member of the collection. Specific error conditions are defined with the VHPI function that accepts a collection.

Future Considerations

1 The formal information model may be extended with notation that reflects operations on an object that may
2 be delegated to collections of such objects. That notation will indicate that the collection must be a
3 homogenous set of objects of the kind that support the operation and its delegation. This will allow the
4 actual C binding of the operation to indicate that a collection handle or a object handle is allowed for this
5 function. The function reference may provide details of what kinds of collections are allowed. This detail
6 should be inferable from the formal information model as well.

8 This concept of a collection may also extended to support other methods for collection construction. For
9 example, it may be reasonable to navigate an association that returns the collection of drivers of a
10 composite with a simple call to `vhpi_handle`.
11

12 3. Interface function overview

13 3.1 Information Access Routines

14 The VHPI interface distinguishes two types of access:

- 15 • accessing a handle of some class type from a reference handle of a given class type; this is a *single* or
16 *one-to-one* relationship.
- 17 • accessing a list of handles of the same class type from a reference handle of a given class type; this is a
18 *multiple* or *one-to-many* relationship.

19 In order to perform these two classes of operations, the VHPI interface defines respectively two
20 mechanisms:

21 `vhpi_handle()` to traverse single relationships and `vhpi_iterator()` in conjunction with `vhpi_scan()` to
22 traverse multiple relationships.

24 Note: A relationship is also called an **association**.

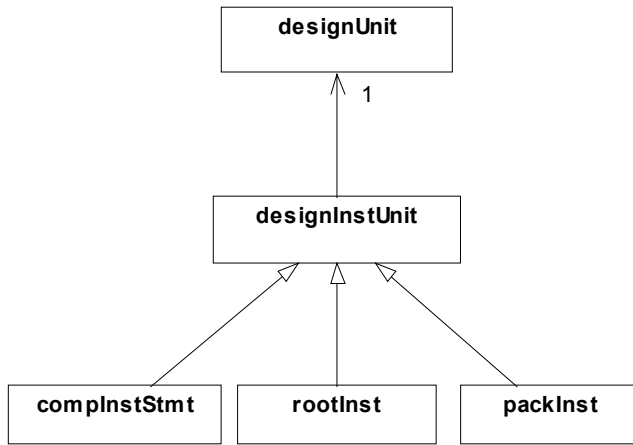

25 Please refer to section 4.1 for a description of the UML notation used by the diagrams in this chapter.

26 3.1.1 Single relationship traversal function

27 The interface provides one function `vhpi_handle()` to traverse one-to-one relationships between objects.
28 The one-to-one relationships are defined by the information model. A one-to-one relationship exists
29 between a reference (source) class and a target (destination) class if there is **at most one** handle of the
30 target class type that can be obtained by traversing this relationship. Given a reference handle of a VHPI
31 kind (`refHdl`), and given a VHPI class kind, the interface returns a handle of that destination VHPI class
32 reflecting the traversal of the relation (example 1). The single relationship can also be marked with a
33 relation name, which name should be used instead of the destination class type (example 2). Named
34 associations are used to disambiguate the relationship to traverse when it is possible to reach the same class
35 type from the same reference handle or to add specific semantic information. These relationship are said to
36 have a tag. The information model defines the set of one-to-one relationships.

38 Example 1: unnamed relationships

39 From a `vhpiCompInstStmK` reference handle, it is possible to access the design unit that is bound to the
40 component instance by following the relationship between a `vhpiCompInstStmK` and the `vhpiDesignUnit`
41 class.
42

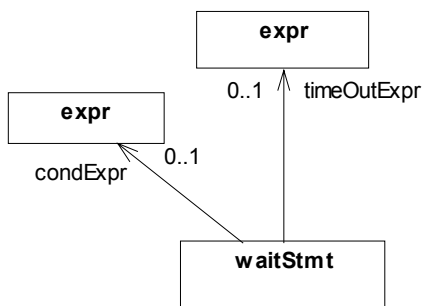

```

1
2
3  vhpiHandleT instHdl, duHdl;
4  void get_binding_info(instHdl) {
5  vhpiHandleT instHdl;
6  switch (vhpi_get(vhpiKindP, instHdl)) {
7      case vhpiCompInstStmtK:
8      case vhpiRootInstK:
9      case vhpiPackInstK:
10     duHdl = vhpi_handle(vhpiDesignUnit, instHdl);
11     vhpi_printf ("design unit name %s", vhpi_get_str(vhpiUnitNameP,
12 duHdl));
13     vhpi_printf("in library %s\n", vhpi_get_str(vhpiLibLogicalNameP,
14 duHdl));
15
16
17 ,
18     break;
19     default:
20     break;
21 }/* end switch */
22 }/* get_binding_info() */
23

```

Example 2: tagged relationships

From a *vhpiWaitStmtK* reference handle, it is possible to access the expression of the condition by following the directed tagged relationship *vhpiCondExpr*. It is also possible to access the time out expression by following the directed tagged relationship *vhpiTimeOutExpr*.

29
30

```

1  vhpiHandleT stmtHdl, condHdl, timeHdl;
2  if (vhpi_get(vhpiKindP, stmtHdl) == vhpiWaitStmtK) {
3      condHdl = vhpi_handle(vhpiCondExpr, stmtHdl);
4      timeHdl = vhpi_handle(vhpiTimeOutExpr, stmtHdl);
5  }
6

```

3.1.2 Iteration functions and `vhpi_handle_by_index`

The interface provides a mechanism to traverse one-to-many relationships. These relationships are defined by the information model. This is a two phase mechanism: first, an iterator handle for the class of objects one wants to iterate on is created and initialized with the function `vhpi_iterator()`, second, a function `vhpi_scan()` is provided to scan the list of handles designated by this iterator. The `vhpi_scan()` function returns a handle for each of the objects of the requested iteration type in the iteration list. `vhpi_iterator()` returns NULL if there is no element in the iteration list. The iteration list can be a dynamic list for callbacks, or transaction iterations. The iteration reflects the current simulation state. Therefore handles to dynamic data returned by `vhpi_scan()` may become invalid as simulation progresses. Callbacks can be added or removed during simulation by either the VHDL simulator or by the VHPI functions such as `vhpi_register_cb()`, `vhpi_remove_cb()`; transactions can be scheduled with `vhpi_put_value()` or `vhpi_schedule_transaction()`.

Note: Unless specified by the information model, an iteration does not define an order therefore user code should not be dependent upon the order the handles are returned in order to be portable.

Example:

Please refer to the scope class diagram.

```

26  vhpiHandleT instHdl, instIter;
27
28  /* get all sub-instances of a scope instance */
29  instIter = vhpi_iterator(vhpiInternalRegions, instHdl);
30  if (instIter)
31  while (instHdl = vhpi_scan (instIter)){
32      vhpi_printf("found instance %s\n", vhpi_get_str(vhpiNameP, instHdl));
33  }
34

```

For any iteration which is qualified as “ordered” in the information model, it is possible to request a handle to a specific object of that iteration by providing an index *n*. The function `vhpi_handle_by_index()` shall take a reference handle which is the same as the one which would be passed to `vhpi_iterator()` and an index *n*, and would return the handle which would have been returned by the *n*th `vhpi_scan()` call.

3.2 Simple property access functions

The interface provides functions to access class properties. There are several classes of properties: boolean or integer properties, string properties, real or physical properties. The interface provides a function to query about boolean or integer properties `vhpi_get()`, a function to retrieve the string value of a string property `vhpi_get_str()`, a function to get the value of a real property `vhpi_get_real()` and a function to get the value of a physical property `vhpi_get_phys()`.

These functions take a handle to an object, the property of interest and respectively return an integer, a string, a real or a physical value. The details are given in the following paragraphs.

3.2.1 Integer or boolean properties

The function `vhpi_get` returns the value of an integer or boolean property.
(`vhpiIntT`) `vhpi_get`(`vhpiIntPropertyT` propertyTag, `vhpiHandleT` handle);

propertyTag: is the tag name of the integer property.

1 handle: is a handle to an object of the information that must possess this property
2
3 returns: an integer constant corresponding to the value of the requested property for the given handle,
4 vhpiUndefined if an error occurred.
5
6 vhpiIntPropertyT is an enumerated standard type of all the integer and boolean properties defined by the
7 interface.
8 vhpiIntT is a VHPI typedef; an implementation should define it to be able to represent the entire range of
9 VHDL integers.
10 #define vhpiUndefined -1
11
12 For boolean properties we define:
13 #define vhpiTrue 1
14 #define vhpiFalse 0
15
16 Specific values are defined for each integer property. For instance, vhpiModeP property can return the
17 following values vhpiInMode, vhpiOutMode, vhpiInoutMode, vhpiBufferMode, vhpiLinkageMode or
18 vhpiUndefined.
19 #define vhpiInMode 1001
20 #define vhpiOutMode 1002
21 #define vhpiInoutMode 1003
22 #define vhpiBuffermode 1004
23 #define vhpiLinkageMode 1005
24
25 Since some integer properties may return negative values; for example the vhpiLeftBoundP or
26 vhpiRightBoundP of a negative range of an array, it may not be possible in all cases to determine that an
27 error occurred by looking at the returned values. In these rare cases, a possible error must be checked
28 according to the error checking mechanism.
29
30
31 **Procedural Interface References:**
32 See “vhpi_get_str()” to get a string property value.
33 See “vhpi_get_real()” to get a real property value.
34 See “vhpi_get_phys()” to get a physical property value.
35
36 Enumeration type for the integer or boolean properties is vhpiIntPropertyT.
37
38 **Errors:**
39 For most of the properties, a returned value of vhpiUndefined will indicate that an error occurred.

40 3.2.2 String properties

41 The function vhpi_get_str returns the value of a string property such as vhpiNameP, vhpiFullNameP...
42 The available string properties which can be queried with this function are listed by the vhpiStrPropertyT
43 enumeration type in the vhpi_user.h header file.
44
45 const PLI_BYTE8 * vhpi_get_str(vhpiStrPropertyT propertyTag, vhpiHandleT handle);
46
47 propertyTag: is the tag name of a string property.
48 handle : denotes a handle to an object which possess the string property.
49
50 returns: a pointer to a static string buffer that has been filled up with the string value of the property
51 successfully retrieved or NULL on failure.
52
53 Notes:

1. The next call to `vhpi_get_str` will overwrite the previous string value.
2. Since VHDL identifiers can contain special and graphic characters, the user must be cautious when using the C string library functions or C `printf` functions when manipulating VHDL strings for name properties. The name property of an extended identifier contains the starting and ending `\` character.

Example:

```

line
1      library lib;
2      use lib.p.all;
3      entity top is
4          postponed assert FALSE report "top level";
5      end top;
6
7      architecture struct of top is
8          signal mySig : integer;
9          for cpu_1 use entity lib.e(a);
10         begin
11             Cpu_1 : mycpu;
12             process (MYSIG)
13                 begin
14                     wait for 1 ns;
15                 end process;
16         end;

```

For a handle to the root instance:

```
vhpiNameP = ":"
```

```
vhpiFullNameP = ":"
```

```
vhpiDefNameP = "work:top(struct)"
```

For a handle to the primary design unit (entity declaration) that is bound to the root instance:

```
vhpiUnitNameP = "lib.top"
```

For a handle to the assert statement in the entity declaration:

```
vhpiNameP = "_0"
```

```
vhpiFullNameP = ":_0"
```

For a handle to the signal declaration in the architecture:

```
vhpiNameP = "mysig"
```

```
vhpiFullNameP = ":mysig"
```

```
vhpiCaseNameP = "mySig";
```

```
vhpiFullCaseNameP = ":mySig"
```

For a handle to the component instance labelled `cpu_1` :

```
vhpiNameP = "cpu_1"
```

```
vhpiCaseNameP: "Cpu_1"
```

```
vhpiFullNameP = ":cpu_1"
```

```
vhpiFullCaseNameP = ":Cpu_1"
```

```
vhpiDefNameP = "lib:e(a)"
```

For a handle to the process statement in the architecture body:

```
vhpiNameP = "_1"
```

```
vhpiFullNameP = ":_1"
```

For a handle to signal `s` declared in package `P`:

```
vhpiFullNameP = ":lib:p:s"
```

Procedural Interface References:

See `"vhpi_get()"` to get an integer based property value.

See `"vhpi_get_real()"` to get a real property value.

See “vhpi_get_phys()” to get a physical property value.
Enumeration type for the string properties is vhpiStrPropertyT.
See ANNEX B for description of each string property.

Errors:

A NULL returned indicates that an error occurred.
The requested property does not apply to this object class kind.
Another property access function must be used for this property class.

3.2.3 Real properties

vhpi_get_real() will return a double, is only used to get the vhpiFloatLeftBound and vhpiFloatRightBound of a floating range. The caller must use the error checking mechanism to determine if an error occurred.

Procedural Interface References:

See “vhpi_get_str()” to get a string property value.
See “vhpi_get()” to get an integer based property value.
See “vhpi_get_phys()” to get a physical based property value.
Enumeration type for the real properties is vhpiRealPropertyT

3.2.4 Physical properties

vhpi_get_phys() will return a vhpiPhysT structure. It is used to get the value of a physical property (for example vhpiResolutionLimitP of the simulation or vhpiPhysLeftBound of a physical type). The value returned is a two member structure.

```
typedef struct vhpiPhysS {  
    PLI_INT32 high;  
    PLI_UINT32 low;  
} vhpiPhysT;
```

Procedural Interface References:

See “vhpi_get_str()” to get a string property value.
See “vhpi_get()” to get an integer based property value.
See “vhpi_get_real()” to get a real based property value.
Enumeration type for the physical properties is vhpiPhysPropertyT.

Errors:

The requested property does not apply to this object class kind.
Another property access function must be used for this property class.

3.3 Look up by name

The interface provides a function to get a handle to an object in the VHDL design hierarchy by relative or absolute name, vhpi_handle_by_name(). This function is operational in the post analysis, post elaboration and runtime domains. This function returns a handle to any object which possesses the vhpiFullNameP property.

3.4 Value manipulation functions

3.4.1 Value access function

The interface provides a function to get the value of an object (`vhpi_get_value`). Only certain classes of objects have a value that can be accessed with this function. Valid classes include VHPI handle kinds denoting VHDL objects, VHDL names or literals. The standard requires `vhpi_get_value` to support the access to values of locally static names only. Note that it is not possible to get the value of any complex expression directly. Subprogram parameter values can only be fetched when the subprogram is executed. The function gets the current value of the designated object, therefore default or initial values of VHDL objects can be fetched at the beginning of simulation, thereafter the value of the object is the simulation value at the present time. The `vhpi_get_value` function takes a handle to an object that possesses the `vhpi_get_value` method, a pointer to a value structure that has been allocated by the user and fills up the appropriate value field in the requested format.

3.4.2 Value formatting function

The interface provides a function to format a value (`vhpi_format_value`). This function takes as the first parameter, the input VHPI value structure, and as the second parameter a VHPI value structure which format field should be set to specify the new format in which the value must be formatted.

3.4.3 Value modification functions

3.4.3.1 Immediate update

The interface provides a function to immediately update the value of an object. Only certain classes of objects can be modified with this function such as handles denoting signals or variables. VHPI classes of objects that are valid for this function are marked in the information by having the `vhpi_put_value` method. Different update modes are available: deposit, deposit and propagate, force until release, force propagate with event, and release the value.

3.4.3.2 Value scheduling

The interface provides a function to schedule a transaction on a signal driver or collection of drivers (`vhpi_schedule_transaction()`). This allows VHPI to participate in signal value update and resolution. Different scheduling modes are available and mimic the inertial and transport mode. A delay can be specified enabling to modify the future waveform of a signal. The function takes a handle to a driver or collection, a value structure, a delay mode and an optional delay time value.

3.5 Foreign Model Support

VHPI supports the creation of foreign architectures and foreign subprograms with semantics equivalent to anything that can be written in VHDL directly.

VHPI supports registering foreign models procedurally with `vhpi_register_foreignf()` and querying registration with `vhpi_get_foreignf_info()`. New drivers can be created with `vhpi_create()` and `vhpi_assert()` emulates a VHDL report statement

3.6 Callbacks

3.6.1 Functions for registration, removing, disabling, enabling callbacks

The interaction between the PLI models or applications and the tool is done via the callback mechanism. The interface provides functions to register, remove, disable or enable callbacks. The interface provides a rich set of callback reasons.

VHPI supports accessing registered callbacks through an iteration mechanism. These can be the complete set of callbacks registered or callbacks registered on signals, ports and so on. Multiple applications can register these callbacks; when iterating on callbacks an application can get a hold of a callback registered by another application.

3.7 Utilities and Miscellaneous Functions

The VHPI functions discussed above cover the full range of information access for the uninstantiated, instantiated, and runtime information models. There remains a small number of utility and miscellaneous functions to complete the VHPI functional interface overview.

3.7.1 Error checking

VHPI calls can produce errors. There are two mechanisms in VHPI to handle them:

- 1) checking a global error status,
- 2) registering a callback on error.

The first mechanism requires calling `vhpi_check_error()` immediately after each VHPI function call to see if the last VHPI function call queued an error. The second is by using an error callback mechanism, where the callback function will be called whenever a VHPI call produces an error. However the drawback of this last mechanism that VHPI does not keep track of which callbacks are registered for which application; therefore a VHPI client may get a callback for an error it did not produce. It is necessary for that VHPI client to recognize its own callbacks: the callback function called on error should be tied to the application or model that produced that error.

Note: John would like to remove the callback on error as it is dysfunctional.

3.7.2 Printing to stdout and log files

The function `vhpi_printf()` writes output to the output channel of the tool which invoked the VHPI application. `vhpi_printf()` uses the same formatting capabilities as the C `printf` function `vhpi_printf()` does not provide the capability to write to VHDL files.

3.7.3 Optional Save/Restart Support

If the VHDL tool supports a save/restart operation, provisions must be made to save private data associated with VHPI applications and foreign models and restore it later. Two routines, `vhpi_put_data()` and `vhpi_get_data()`, support this functionality.

Francoise: Should we mention anything about reset even though it does not add any other interface functions?

3.7.4 Miscellaneous Functions

`vhpi_compare_handles()` – checks if two handles refer to the same object.
`vhpi_control()` – provides some control capabilities over the tool, such as stopping or finishing execution.
`vhpi_get_time()` – returns the current simulation time
`vhpi_get_next_time()` – returns the next simulation time at which some activity is scheduled
`vhpi_protected_call()` – executes operations on variables of a protected type
`vhpi_release_handle()` – releases resources associated with a handle

4. The VHDL PLI information model

4.1 Formal notation

We use the standard Unified Modeling Language (UML) to formally express the VHPI information model. UML is a graphical language to model object-oriented software design. It defines a rigorous notation and a meta model of the notation (diagrams) that can be used to describe object-oriented software design. We use the *class diagram* technique of UML to express the VHDL PLI information model. A class diagram specifies the VHPI class types and the way they are connected together. In UML, class inheritance is denoted by a hollow arrow directed towards the parent class. Relationships between classes are called *associations* and are denoted by straight lines between classes. Associations have descriptive parameters such as *multiplicity*, *navigability* and *role names*.

UML notation quick reference

A class

A member class

The link shows **inheritance** between a class and its derived classes. A derived class inherits properties and operations from its parent classes. The hollow arrow points to the parent class.

An expanded class shows two compartments, the first one displays the **properties** (attributes in Object Oriented terminology) with their names and return type, the second one displays the **operations** (methods in Object-Oriented terminology) that are defined within this class. Properties and operations inherited from parent classes may not appear in the compartment boxes of the derived classes.

Associations

Associations are links between classes that represent their inter-relationships.

Navigability, multiplicity and role names can be used to further describe the relationship.

Navigability expresses the direction of access and is represented by an arrow. An association can be bi-directional in which case arrows may be shown at both ends.

Multiplicity expresses the type of relationship between the classes: singular (one, zero or one), multiple (zero or more, one or more) and is represented by numbers at the end of the association to which it applies. It can be one the following:

- 1 for access to one object handle
- 0..1 for access to zero or one object handle
- * for access to zero or more object handles of the same class
- 1..* for access to one or more object handles of the same class

A **role name** is a tag name on one end of the association. It may be used to indicate more precisely the relationship or to distinguish this relationship from another relationship that leads to an object of the same class. In the example below, role-1 is the name of the relation that accesses an object of class-2 from an object of class-1. The relationship it denotes is a singular relationship.

In the diagrams, we use the following convention:

if a role name is not specified, the method name for accessing the object pointed by the arrow is the target class name.

class-1 accesses class-2, method name is role-1

scope class accesses decl class, method name is decls.

The VHPI iteration or one-to-many method is modeled by an association with a multiplicity of either zero or more (*), or one or more (1..*) to indicate that the iteration may contain zero elements or will contain at least one element. The direction or navigability indicates the class of the handles created by the iteration. In the example above, we show that there is a one-to-many relationship between a scope class and a decl class. A singular or one-to-one method will be represented by a navigable association with a multiplicity of one (1) if the method should always return a handle of the destination class or a multiplicity of zero or one (0..1) if the method may not return a handle. In the example above, the diagram shows a one-to-one relationship that allows to traverse the association named “role-1” between a handle of class-1 and a handle of class-2. Note that the diagrams only express the possible access flow; for example there is no method that allows to get a handle of class-1 from a reference handle of class-2. An iteration qualified as “ordered” indicates that the elements of the iteration are always returned in a given order and that this order must be the same in all VHPI compliant implementations. If an iteration is qualified as ordered, it also means that the `vhpi_handle_by_index` function is available on the reference handle and can be used to return the n^{th} element of the ordered iteration.

4.2 Classes overview

The information model is partitioned into a few UML packages, each package contains several class diagrams which are related to a given capability. A class diagram shows the traversal relationships between related classes.

- the standard hierarchy package includes class diagrams used to traverse VHDL design hierarchy, it typically describes the hierarchy capability set,
- the standard design unit package includes class diagrams to VHDL design units, and the lexical scope class diagram..
- the standard declaration package includes class diagrams describing object declarations.
- the standard type package includes class diagrams describing types and subtypes.
- the standard spec package includes class diagrams describing attributes, disconnection, and configuration specifications.
- the standard subprogram package includes class diagrams describing subprogram declarations and subprogram call access.
- the standard statement package includes class diagrams describing concurrent and sequential statements.
- the
- the standard expression package includes class diagrams describing expressions.
- the standard connectivity package includes class diagrams describing the drivers and port connections access.
- the standard engine package includes class diagrams describing tool access
- the standard callback package includes class diagrams describing callback access
- the standard foreignf package includes class diagrams describing access to to foreign models.
- the standard meta package includes class diagrams of the base class, iterator and collection classes.

The class hierarchy defined by the VHPI model is the following. Each indentation indicates that a lower level in the hierarchy and that the indented class type denotes a child class of the immediately preceding class.

(*) indicates a class that inherits from multiple ancestor classes.

All classes inherit from the `vhpiBase` class.

- 1 The class “vhpiToolK” designates the simulator, elaborator or tool that is executing the VHDL model.

1 The base and null classes are meta-classes; which means that they do
2 not belong to the information model of VHDL but are defined for modelling
3 the access.

4 (1) The base class is the top of the class hierarchy.
5 It has 2 properties the `vhpiKindP` and `vhpiKindStrP` properties.
6 All defined classes inherits from the base class.

7

8 (2) The Null class denotes the VHDL elaborated or uninstantiated design.
9 It is named the null class because a null pointer handles is used to refer to it.
10 For example: `vhpi_handle(vhpiRootInst, NULL)` will return the top
11 level instance of the current elaborated VHDL design.
12 `vhpi_get_phys(vhpiResolutionLimitP, NULL)` returns the resolution.

13

14 (*) denotes multiple inheritance for the class
15 (?) Do we need this class?

1 All traversal methods and properties defined by the information model if not implemented shall return a
2 non implemented error message.

3

4 The information model is organized as a set of UML packages, each one containing one or more UML
5 class diagrams. A UML package is a logical directory containing class diagrams depicting related
6 functionality.

7

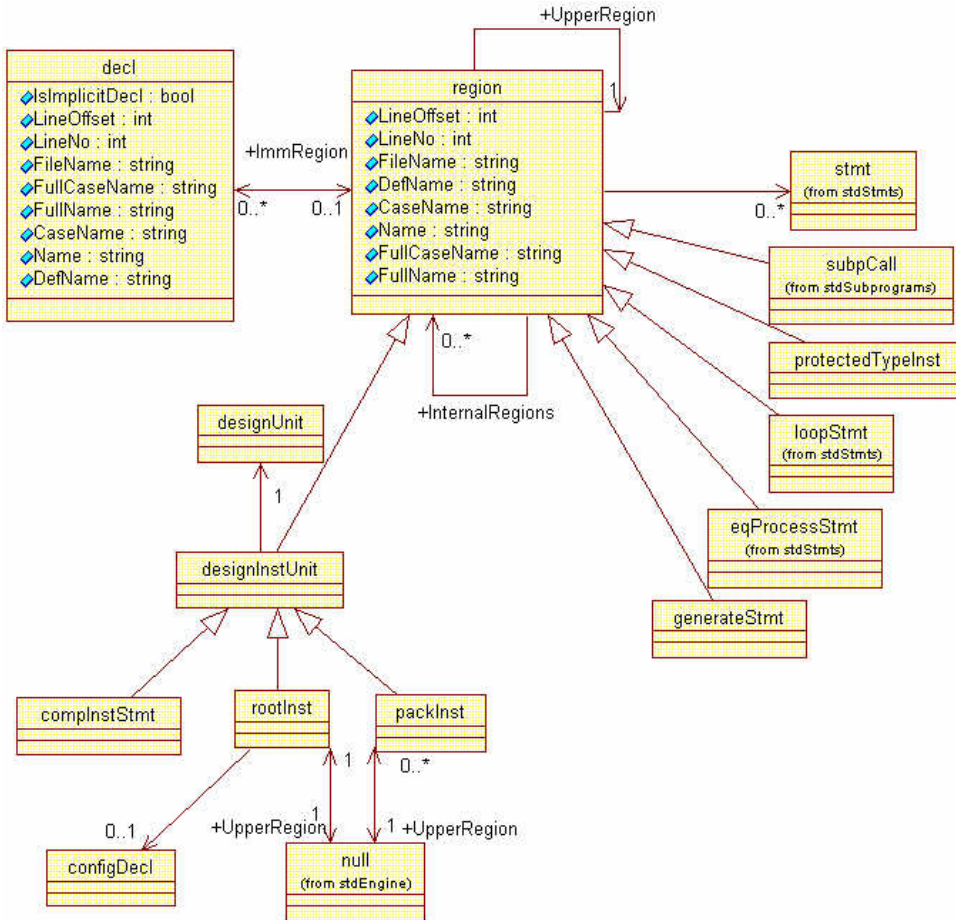

8

4.3 Standard hierarchy package (hierarchy capability set)

4.3.1 The region inheritance class diagram

This access represented by this diagram is part of the hierarchy capability with the exceptions of:

- 1) Access to a vhpiLoopStmt and vhpiSubpCall is only part of the dynamicElab capability.
- 2) Iteration on vhpiStmts is part of the static access capability.
- 3) The one to one relationship from a vhpiRootInstK class to a vhpiConfigDecl class is part of the post analysis access capability set.

Note:

1. Iteration on internal regions may return any region kind except loopstmt and protectedType kinds. A variable of a protectedType creates a protected type region. Upper region of a protected type shall return the region of the variable declaration. The name of a protected type region is the name of the variable. The fullname of a protected type region is the fullName of the variable. vhpi_handle_by_name of such fullName shall return a handle to the variable.

Deleted: ¶

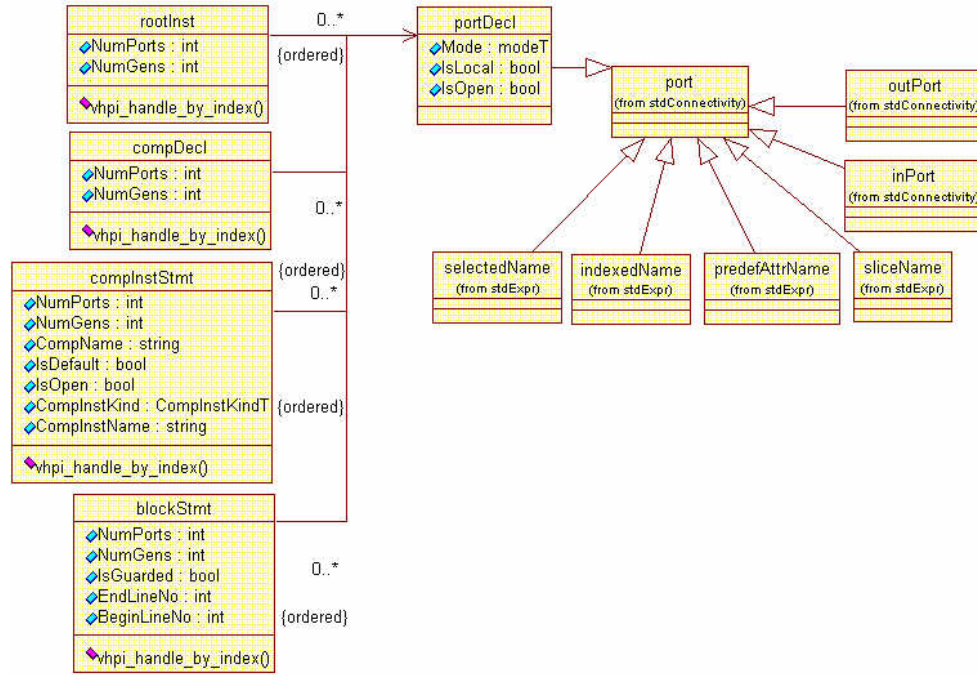

Notes:

- Iteration on internalRegions only return the elaborated regions.
- Iteration on stmts return all statements, instantiated or uninstantiated.

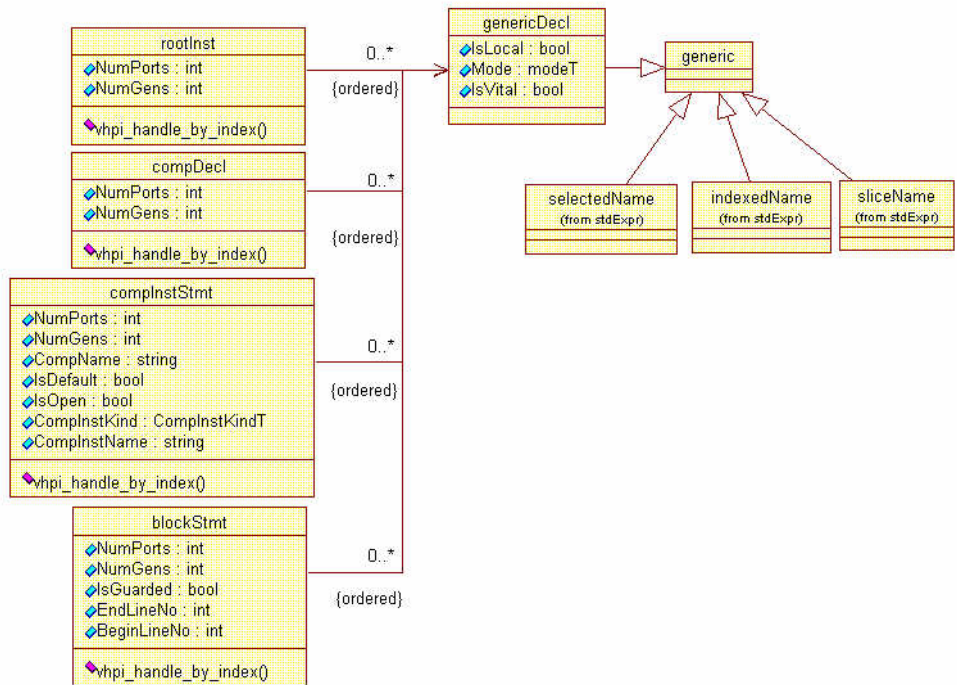

4.3.2 The port class diagram

The access described by this diagram is part of the hierarchy capability.

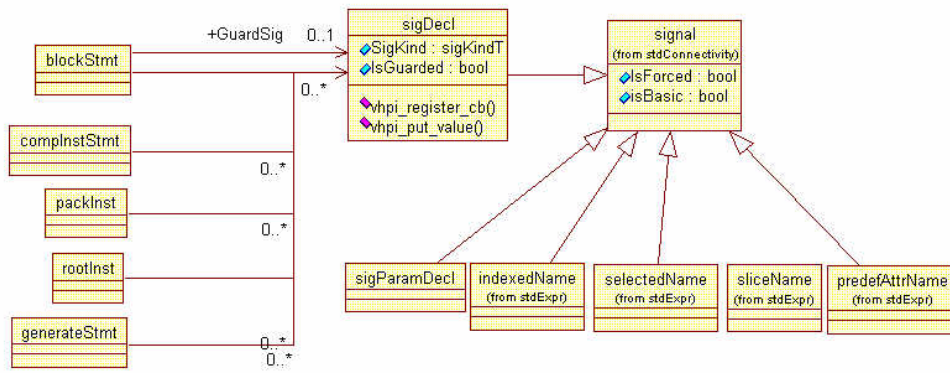

The access described by this diagram is also part of the post analysis capability with the exception that a vhpiRootInstK class of object may never be obtained in the post analysis domain.

4.3.3 The generics class diagram

1 4.3.4 The signals class diagram

2

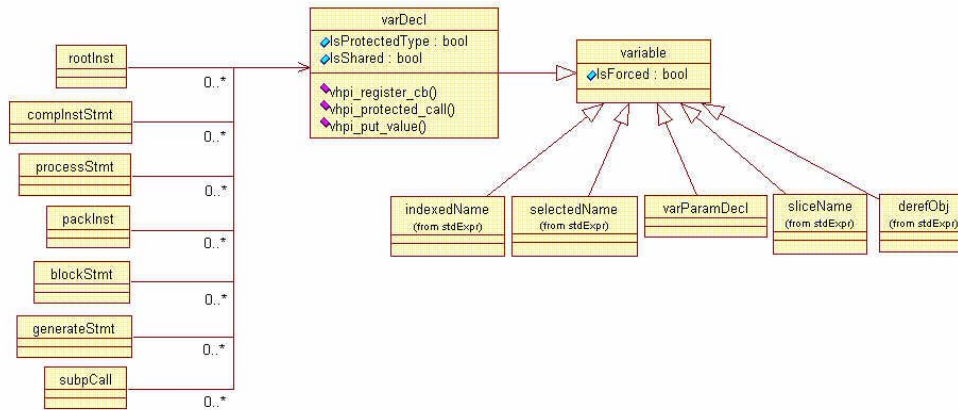

4.3.5 The variable class diagram

The access described by these diagrams is part of the static access and post analysis capabilities with the exception of `vhpi_put_value` which is part of the debug and runtime capability.

In addition, `vhpi_put_value` on is also part of the basic foreign model capabilities.

`vhpi_register_cb` for `varDecl` is also part of the debug and runtime capabilities and basic foreign model capabilities.

`vhpi_protected_call()` is also part of the debug and runtime capability.

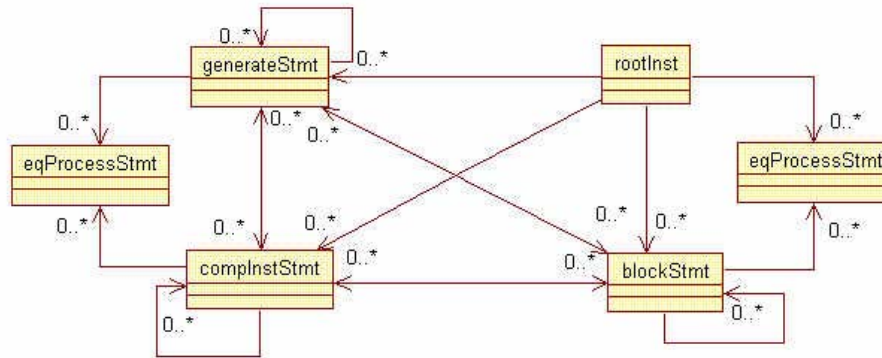

1

4.3.7 The structural class diagram

The access described by this diagram is part of the hierarchy capabilities.

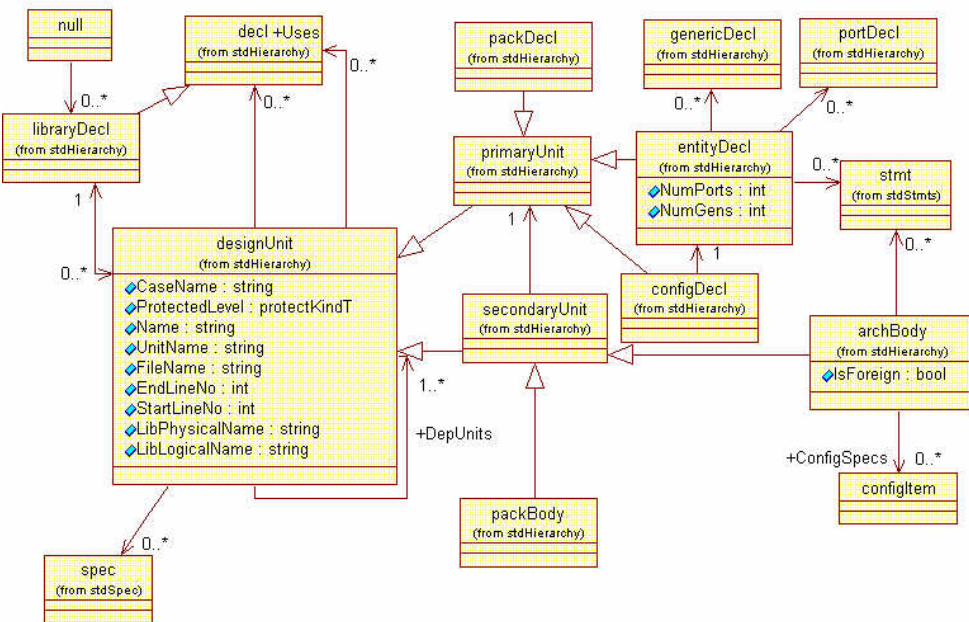

Notes:

- The iterations are specialized iterations of the `vhpiInternalRegions` iteration. In a pure VHDL design, they are equivalent to iterating on `vhpiInternalRegions` and filtering a special kind of region. These iterations are useful when traversing a mixed language design. (May be put an informative Annex on use of VHPI and VPI when traversing mixed language designs.)
- These iterations only return handles to elaborated regions.

4.4 Standard uninstantiated package (post analysis capability set)

4.4.1 The design unit class diagram

This diagram describes access which is part of the post analysis and static access capabilities.

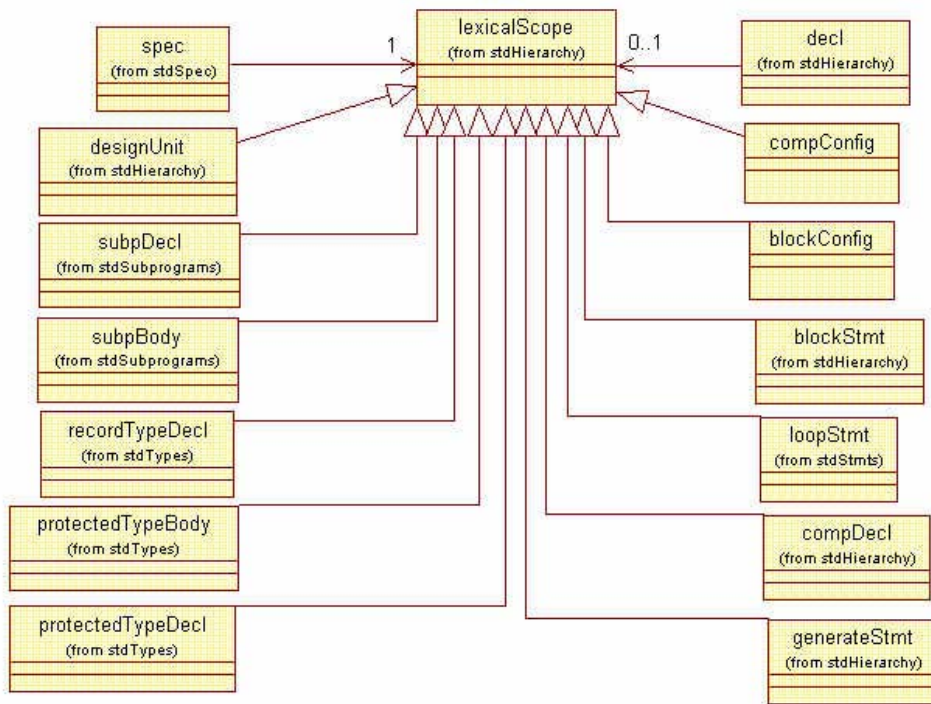

Note:

6. The iteration vphiUses returns external declarations referenced by the design unit.
7. Access to the library declarations is not directly available but can be extrapolated from the uses iterations.

4.4.2 The lexical scope diagram

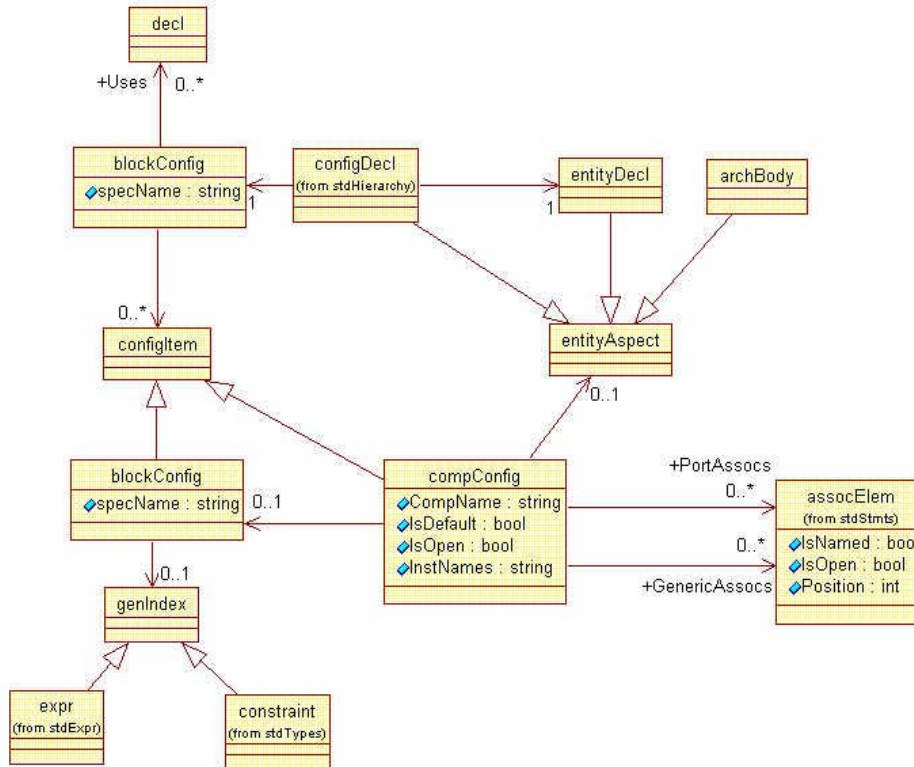

The access described by this diagram is also part of the post analysis capabilities.

1
2

3 4.4.3 The configuration declaration class diagram

4 The access described by this diagram is part of post analysis capability.

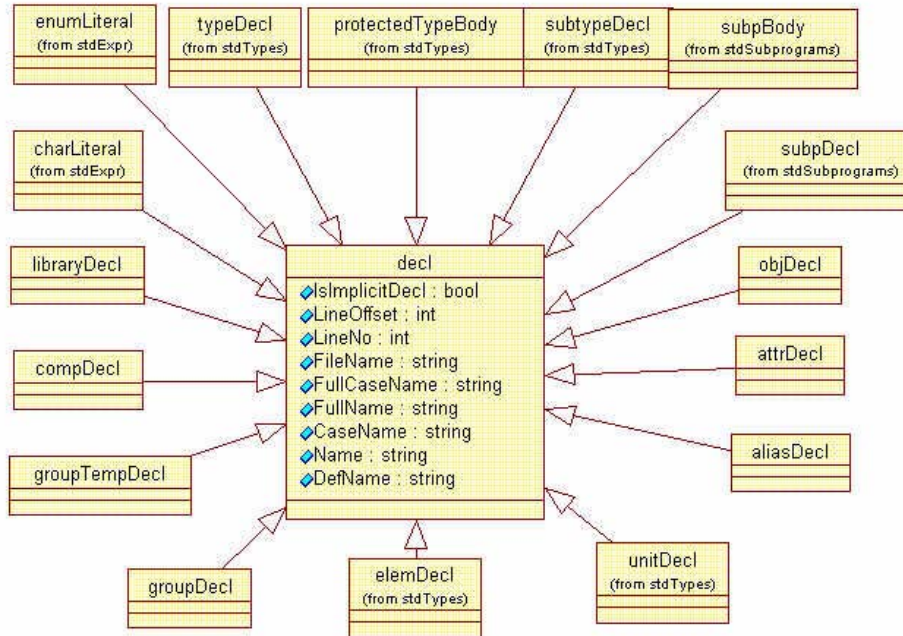

Notes:

8. The iteration `vhpiUses` returns the external declarations referenced by the design unit.
9. If `vhpiIsOpen` or `vhpiIsDefault` is true, then `vhpiEntityAspect`, `vhpiPortAssocs` and `vhpiGenericAssocs` shall return null.
10. The binding indication is obtained from the `compConfig` by traversing to the `entityAspect`. An entity aspect can either be a `entityDecl`, a `configDecl` or an `archBody`.
11. `vhpiInstNames` returns "all", or "others" or the list of the instance names as it appears in VHDL,

4.5 The standard declaration package (hierarchy and static capability sets)

4.5.1 The declaration class inheritance diagram

The access described by this diagram is part of the static access and post analysis access capabilities.

Notes:

12. Iteration on vhpDecls does not return implicit declarations.

4.5.2 The object class diagram

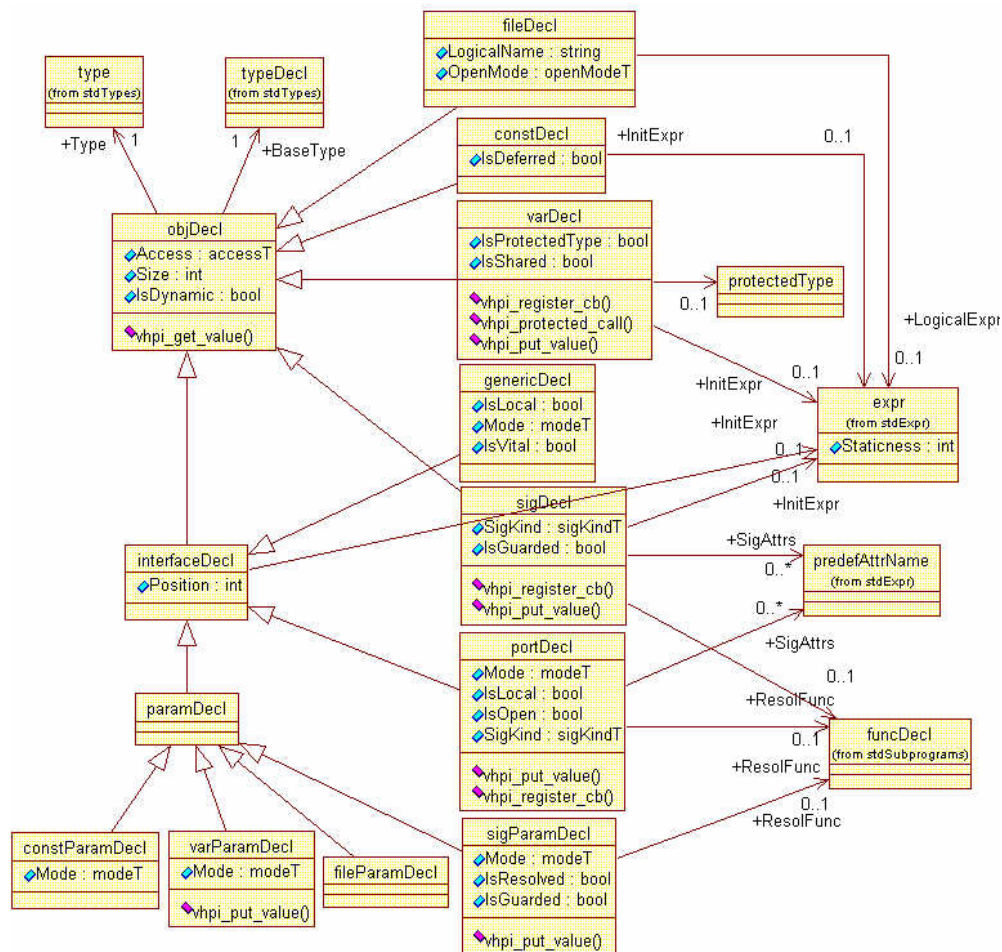

The hierarchy capability includes the access described by this diagrams with the exception of getting values and modifying object values, registering callbacks and protected calls.

The post analysis capability includes the access described by this diagrams with the exception of getting values and modifying object values, registering callbacks and protected calls.

Deprecated:

- One-to-one relationship `vhpiSubtype` from `objDecl` to `vhpiSubtypeIndicK`
This method is deprecated in favor of the `vhpiType` one-to-one relationship which provides a more direct and simplified way of obtaining the type of an object. The `vhpiSubtypeIndicK` kind is deprecated.
- `vhpiTypeMark` class is renamed `vhpiType`.
The type of the object may be an implicit declared type which does not have a type name, hence the renaming of `vhpiTypeMark` to `vhpiType` which does not imply that the type has a type name. The rename of the method also provides a recursive way of traversing the type hierarchy.

Deprecated diagram:

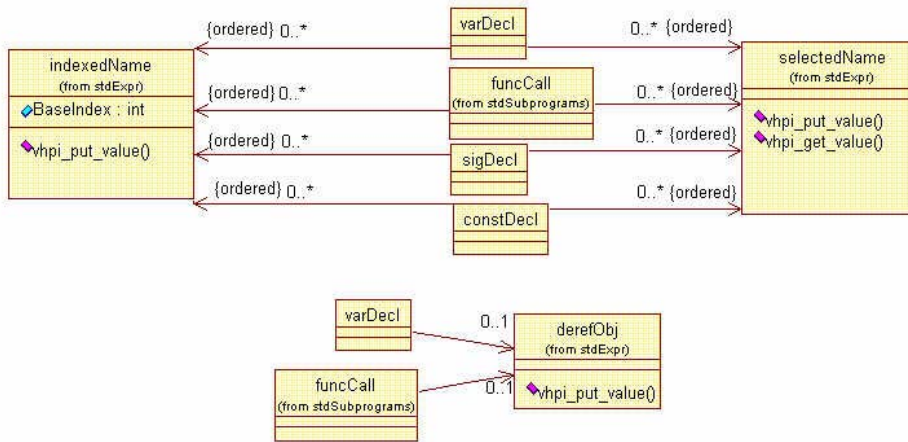

Notes:

13. If a variable is of a protected type (vhpiIsProtectedType property return TRUE), the 1-to-1 relationship vhpiProtectedType shall return the protected type region instance of this variable. The protectedType name is the same as the name of the variable.
14. If the variable is a shared variable of a protected type, access or modification of the values of the local declarations of the variable protected type region shall be done through a vhpi_protected_call.
15. vhpi_get_value() can only return the name of the file which has been opened when applied to a fileDecl.
16. The property vhpiAccessP can return either vhpiNoAccess or a combination of the bit flags vhpiRead, vhpiWrite, vhiConnectivity. This property can be used to determine any tool restricted access on a given object declaration.

Issue: is this property applicable to a fileDecl?

4.5.3 The composite object class diagram

The hierarchy capability includes the access described by this diagrams with the exception of getting values and modifying object values.

Notes:

17. The `vhpiDerefObj` relationship returns NULL if the variable declaration or function call is not instantiated. `deref`

Can I ask for the prefix? If it represents an actual memory location, prefix is undefined, how you get there may have multiple paths?

4.5.4 The alias declaration diagram

The access described by this diagram is part of the static access capability.

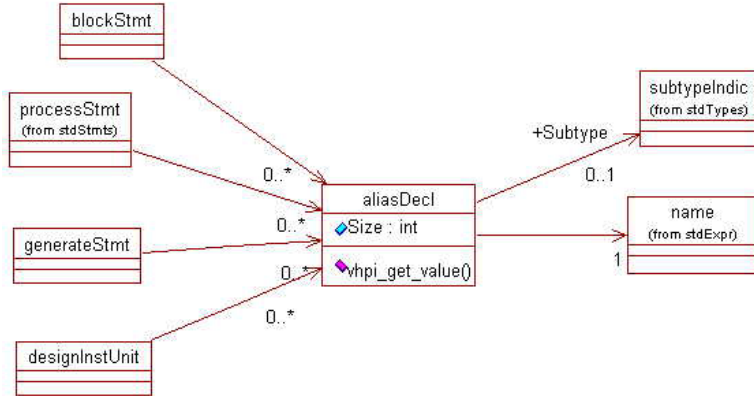

The access described by this diagram is part of the post analysis access capability.

Note: Size property and vhp_i_get_value will return a value for a locally static expression, of object aliases.

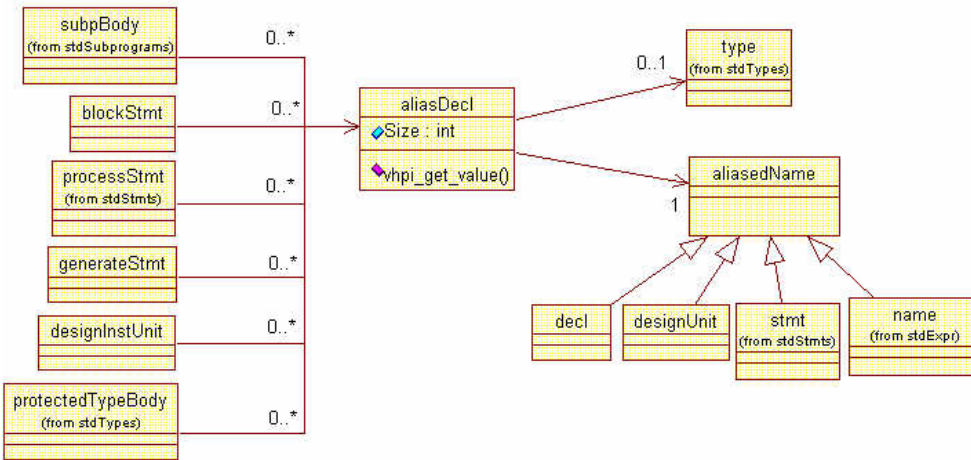

Note: Iteration on vhp_iAliasDecls, attrDecls, BlockStmts, compInstStmts

and sensitivities can only applied to the sub-class of the class
region for which they be possible.

Deprecated diagram with respect to the vhp_iSubtype method:

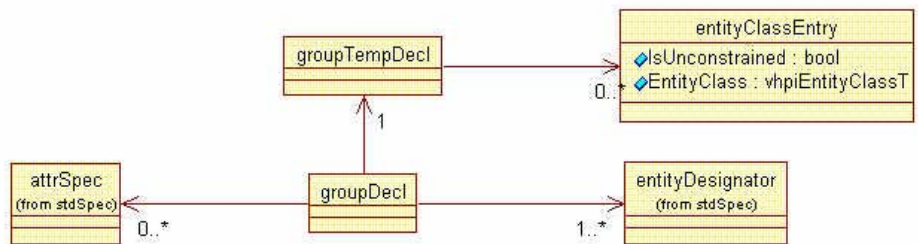

New diagram:

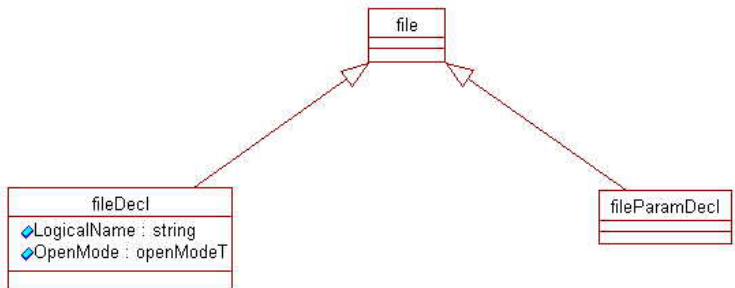

1 Notes:
2 18. `vhpi_get_value` only applies to alias of objects or of names.
3 19. `vhpiType` returns a null handle for non-object aliases..It returns the resulting type of the alias as
4 defined by the rules in the VHDL LRM alias Declaration section.

1 4.5.5 The group declaration diagram

2 The access described by this diagram is part of the static access and post analysis capabilities.

4
5
6
7
8 4.5.6 The file inheritance diagram

4.6 The standard type package (static access capability set)

4.6.1 The type and subtype class diagram

The access described by this diagram is part of the hierarchy access with the exception of access to the attribute specifications. Access to attribute specification is part of the static access.

The access described by this diagram is also part of the post analysis capabilities.

Replace typemark with type, replace retrunTypeMark with ReturnType, remove subtypeIndic. Make type class inherit from constraint

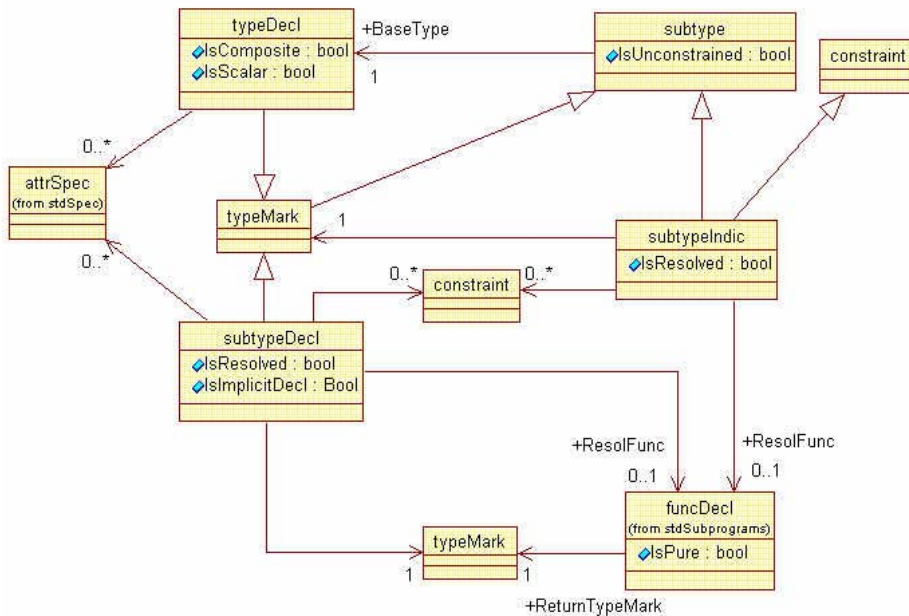

Deprecated:

- vhpTypeMark one-to-one relationship is renamed vhpType, vhpTypeMark class is renamed vhpType class.
- vhpSubtypeIndicK class is deprecated
- vhpSubtype class is deprecated
- vhpIsAnonymous is deprecated

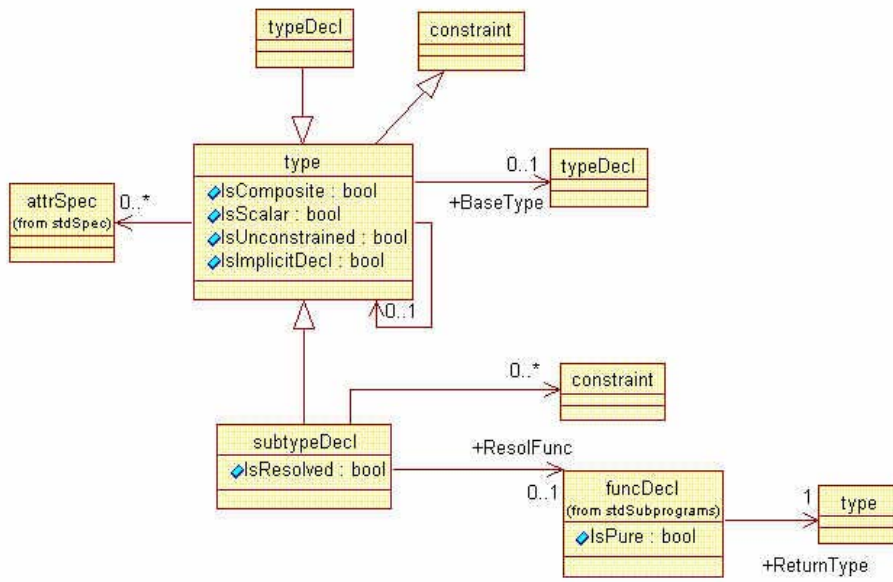

Remove subtype class, move isUnconstrained to the type class. BaseType relationship 0..1 from type to typedecl. BaseType always returns null from a typedecl. vhpType always returns null from a typedecl. Move IsComposite to class type. Move isImplicitDecl to type class. Remove isAnonymous

Move isScalar to the type class

Deprecated diagram:

New diagram:

Ask a question to Peter on where to provide types examples in the LRM.

Notes:

20. The base type of a type is not the base type defined by the VHDL LRM but the user defined type.

21. The recursive `vhpiType` method ends at the base type.

22. The `vhpiBaseType` of a `TypeDecl` handle returns null.

4.6.2 The type inheritance class diagram

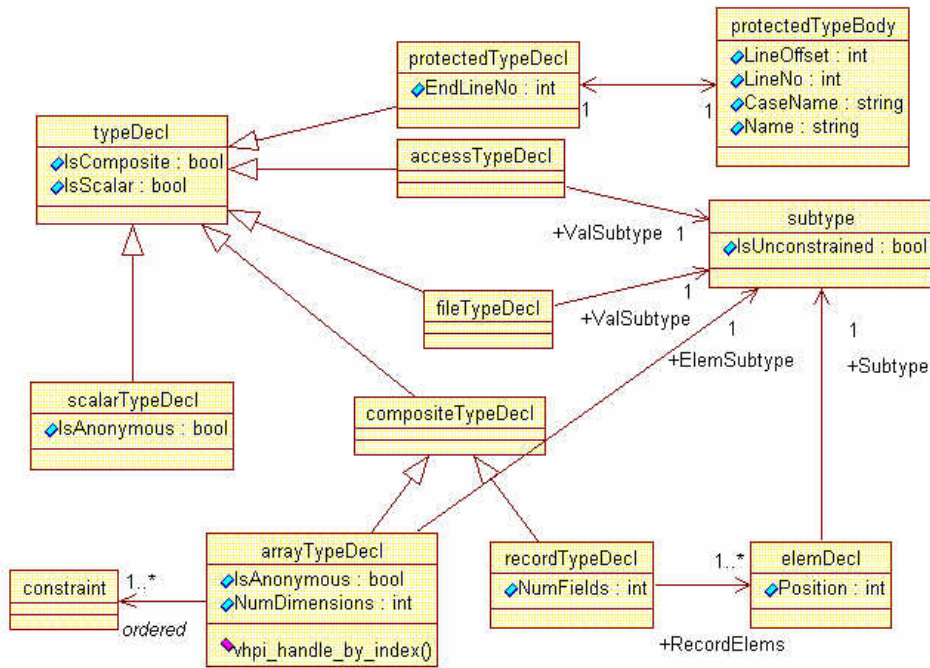

The access described by this diagram is part of the hierarchy access and post analysis capabilities.

Deprecated:

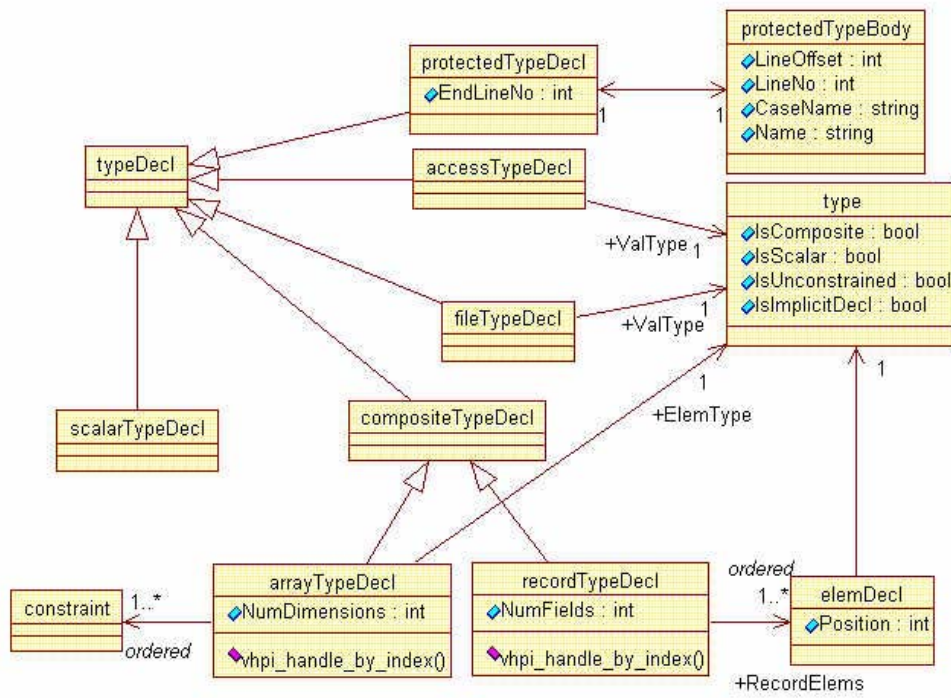

Replace subtype class with type class replace the tags valsubtype with valtype, elemsubtype with elemtype and subtype with type,
Remove isAnonymous

- vphiSubtype class is deprecated.
- The tagged relationships vphiValSubtype, vphiElemSubtype and vphiSubtype are deprecated.
- vphiIsAnonymous is deprecated.

Deprecated diagram:

New diagram:

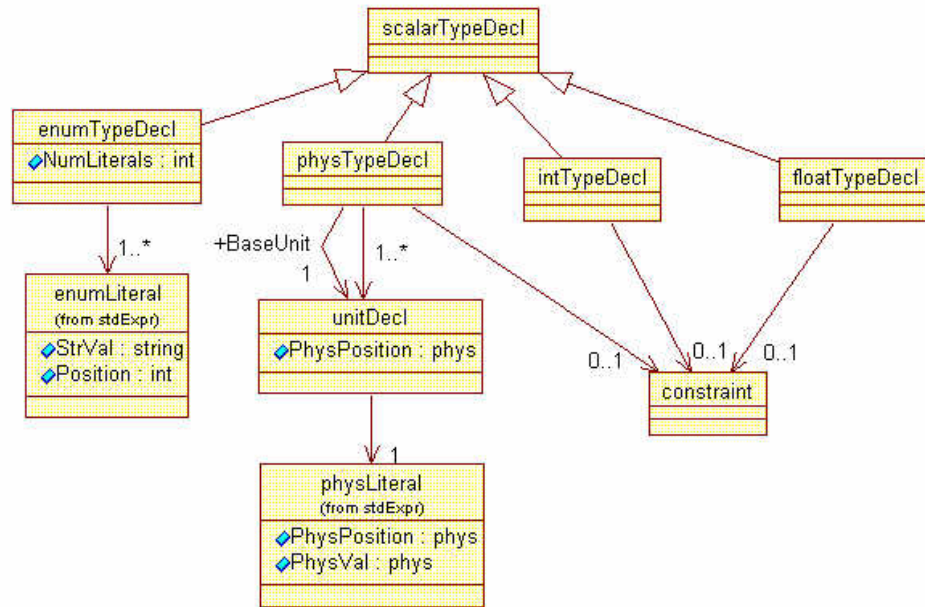

Notes:

23. `vmpiBaseType` should return the user defined type or the predefined type definition.

4.6.3 The scalar type class diagram

The access described by this diagram is part of the hierarchy access and post analysis capabilities.

4.6.4 The constraint class diagram

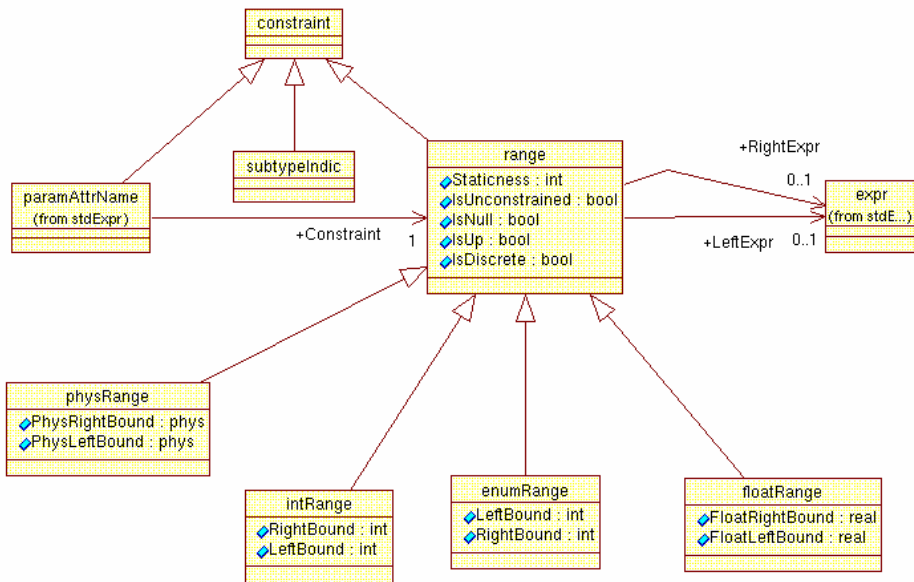

The access described by this diagram is part of the static access (unless it is needed to traverse the subtype to get the value of an object and in that case it should be part of the hierarchy capability)

The access described by this diagram is also part of the post analysis capabilities.

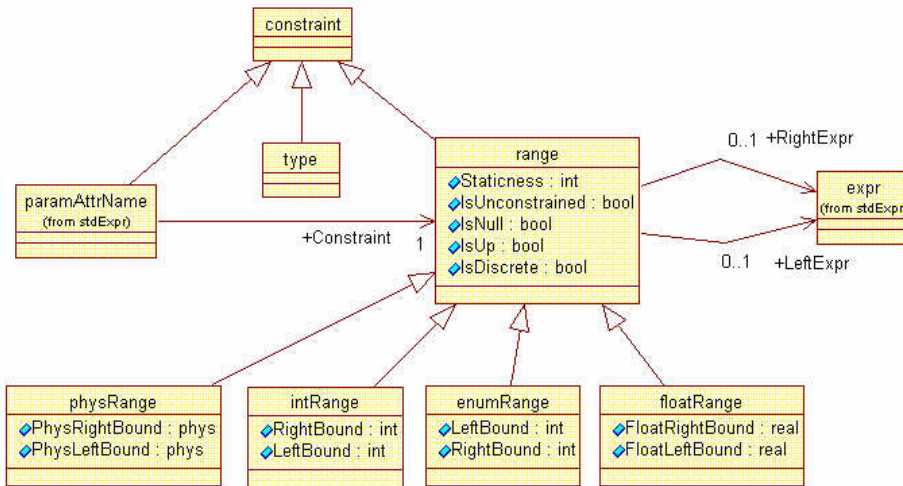

Deprecated:

- `vhpiSubtypeIndicK` class is deprecated.

Deprecated diagram:

New diagram:

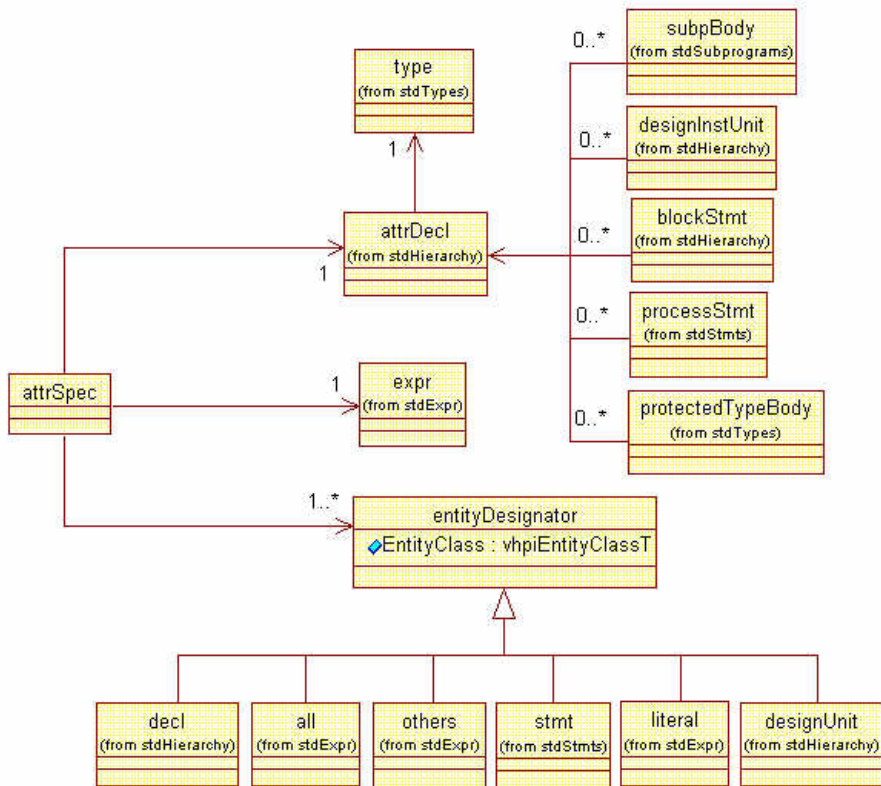

1 Notes:
2
3 24. vhpConstraint from a paramAttrName returns the range represented by the attribute 'range or
4 'reverse_range as described by the VHDL LRM.

4.7 The standard specification package (static access capability set)

4.7.1 The attribute declaration and specification class diagram

The access described by this diagram is part of the static access and post analysis capabilities.

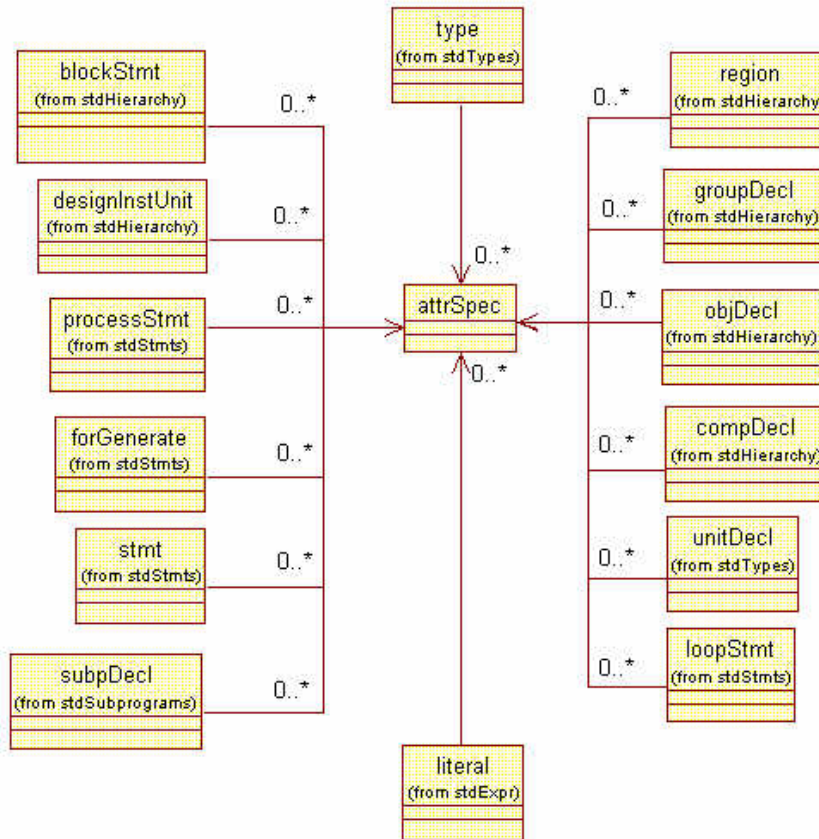

1

2 4.7.2 The attribute specification associations

3 The access described by this diagram is part of the static access and post analysis capabilities.

4

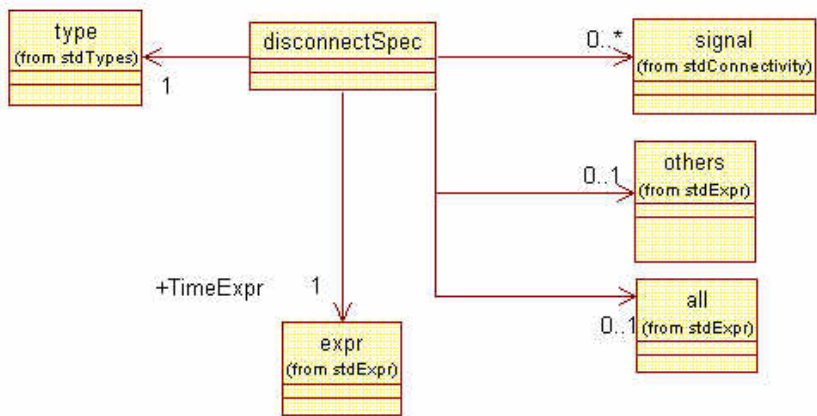

5

6

7

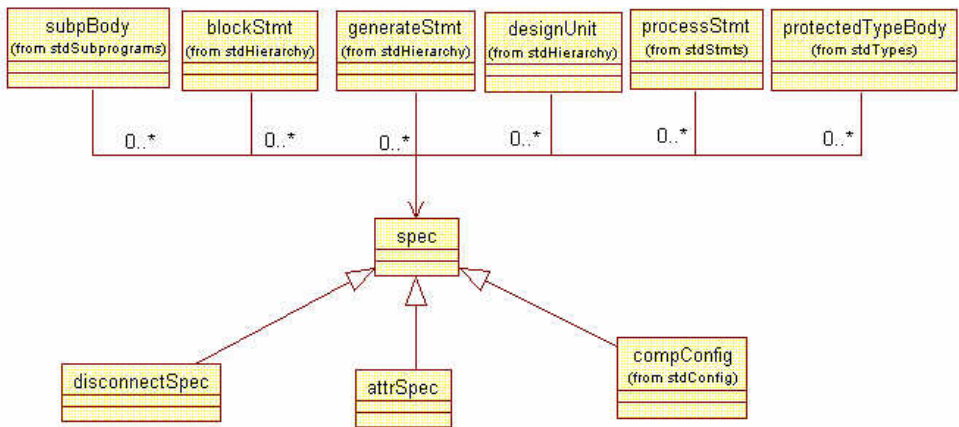

1 4.7.3 The disconnection specification class diagram

2 The access described by this diagram is part of the static access and post analysis capabilities.

9 4.7.4 The specifications diagram

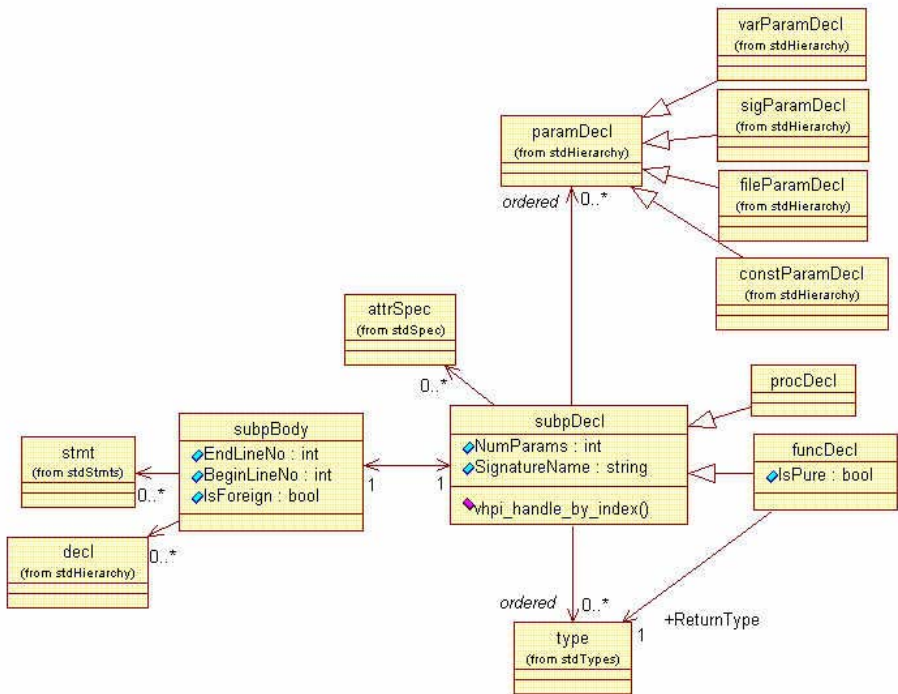

10 The access described by this diagram is part of the static access and post analysis capabilities.

4.8 The standard subprogram package (static access and dynamic elab capability sets)

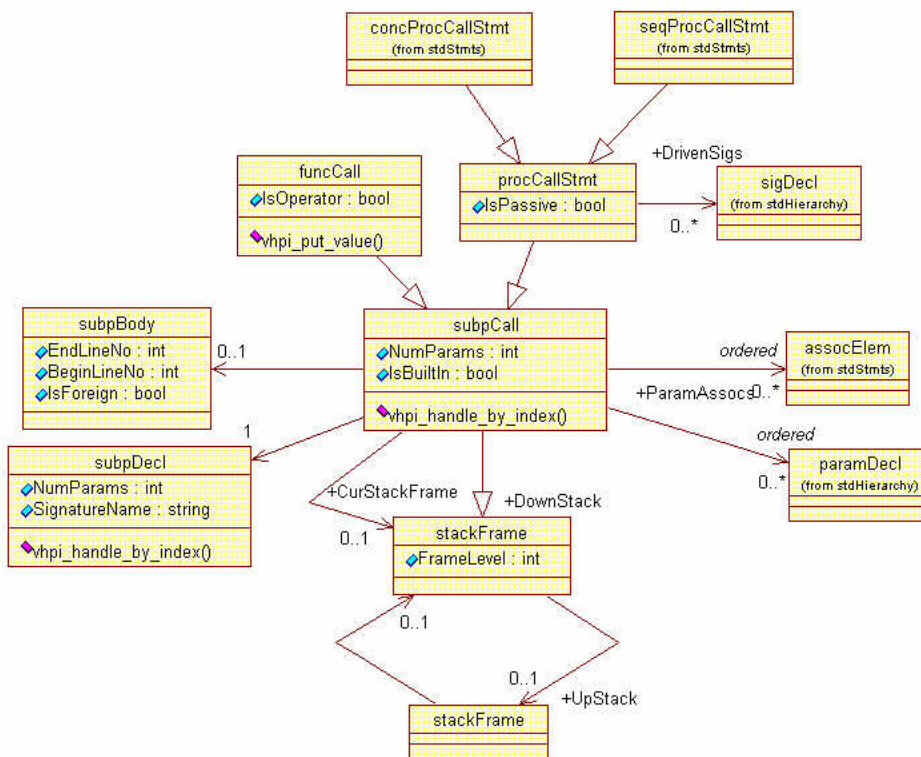

4.8.1 The subprogram declaration class diagram

The access described by this diagram is part of the static access and post analysis capabilities.
The access described by this diagram is part of the basic foreign model capability. However if the subbody is a foreign model, iteration on statement, declarations and attribute declarations shall return NULL.

4.8.2 The subprogram call class diagram

The access described by this diagram is part of the basic foreign model capability.
The access described by this diagram is part of the dynamic elaboration access capability except for vhp_i_put_value on function calls.
The access described by this diagram is part of the static access capability with the exception of access to and from stackFrames, vhp_i_put_value of function calls and iteration on driven signals.
Iteration on driven signals is part of the connectivity capability.

Notes:

25. Iteration on paramDecls from an instantiated subpCall (active) returns the formal parameters to which the associations of the actuals are in effect
26. A subpCall is only a stackframe if the subpcall is instantiated
27. Handles obtained from a stack frame which represents a protected type method of a shared variable do not require a vhp_i_protected_call as the lock has already been obtained by the subprogram executing.

28. The property vhp_iIsOperatorP is TRUE if a function call denotes an operator call. There are 3 categories of operators: predefined operators from the TEXTIO or STD package, built-in or accelerated operators for example operators defined in the stdlogic or vital packages, user-defined operators.
29. When applied to a subpCall handle, the property vhp_iIsBuiltInP returns TRUE if the subpboday is unavailable and has a private implementation. If the property return FALSE and the subpCall is a

Deleted: ¶

Formatted: Bullets and Numbering

1 funcCall for which the property vhpIsOperatorP is TRUE, the function call denotes a user defined
2 operator call.

4.9 The standard statement package (static access capability set)

4.9.1 The concurrent statement class diagram

The access described by this diagram is part of the static access capability.

Note: The iteration on sensitivity only applies to concurrent statements : concurrent assert statement, concurrent signal assignment statement and concurrent procedure call statements.

Refactoring the eqProcessStmt with assertion/sigassign/proccallstmt

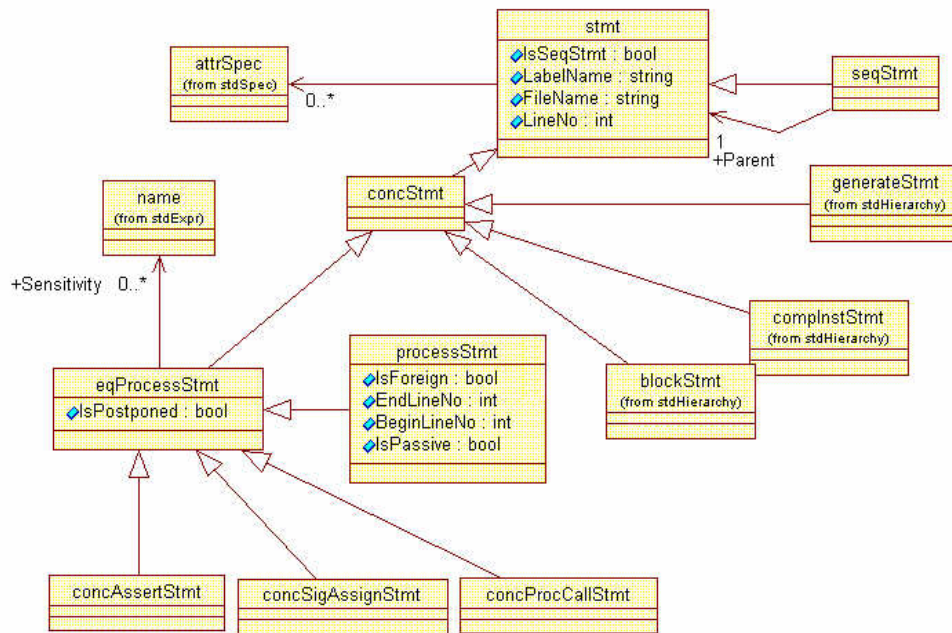

Or add 6 classes concassert, concsigassign...

Note:

30. Explain what is the sensitivity (explicit or as inferred by the LRM). Union of the wait sensitivity?

Static sensitivity: list of the signals on the explicit sensitivity list. Return null for the processes having wait stmts.

Formatted: Bullets and Numbering

4.9.2 The structural statement class diagram

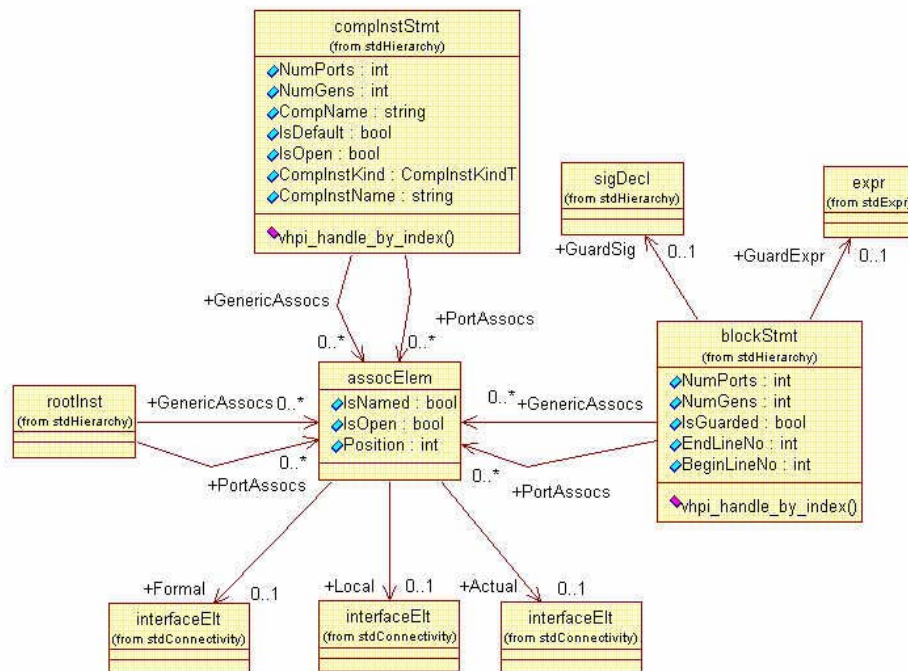

The access described by this diagram is part of the static access capability except with the exception of accessing the formal of an association element which is part of the connectivity capability.

The access described by this diagram is part of the post analysis capability with the following exception:
Access to the formal of an association element is part of the connectivity capability.

Notes:

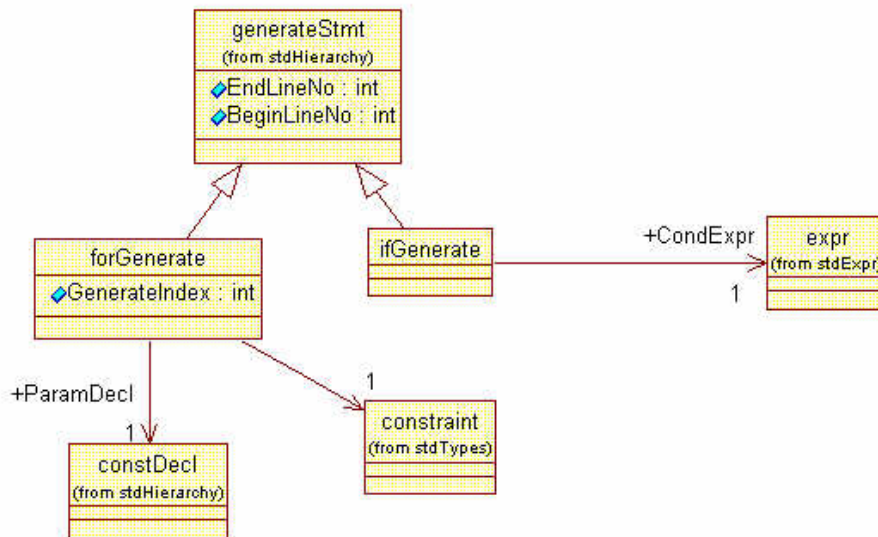

31. If `vhpiCompName` returns null then the component instance statement is a direct instantiation, otherwise if `IsDefault` is true, there is no component configuration, and the name of the bound entity is the same as the name of the component, else if `isDefault` is false, there is either a component configuration in the architecture containing this component instance or in a configuration declaration.
32. The position of an `assocElem` is the position of the formal in the interface list.
33. Formal is only accessible from an association element obtained from a direct component instance statement. Local is only accessible from an association element obtained from a non direct component instance statement.

Formatted: Bullets and Numbering

4.9.3 The generate statement class diagram

The access described by this diagram is part of the static access and post analysis capability.

Notes:

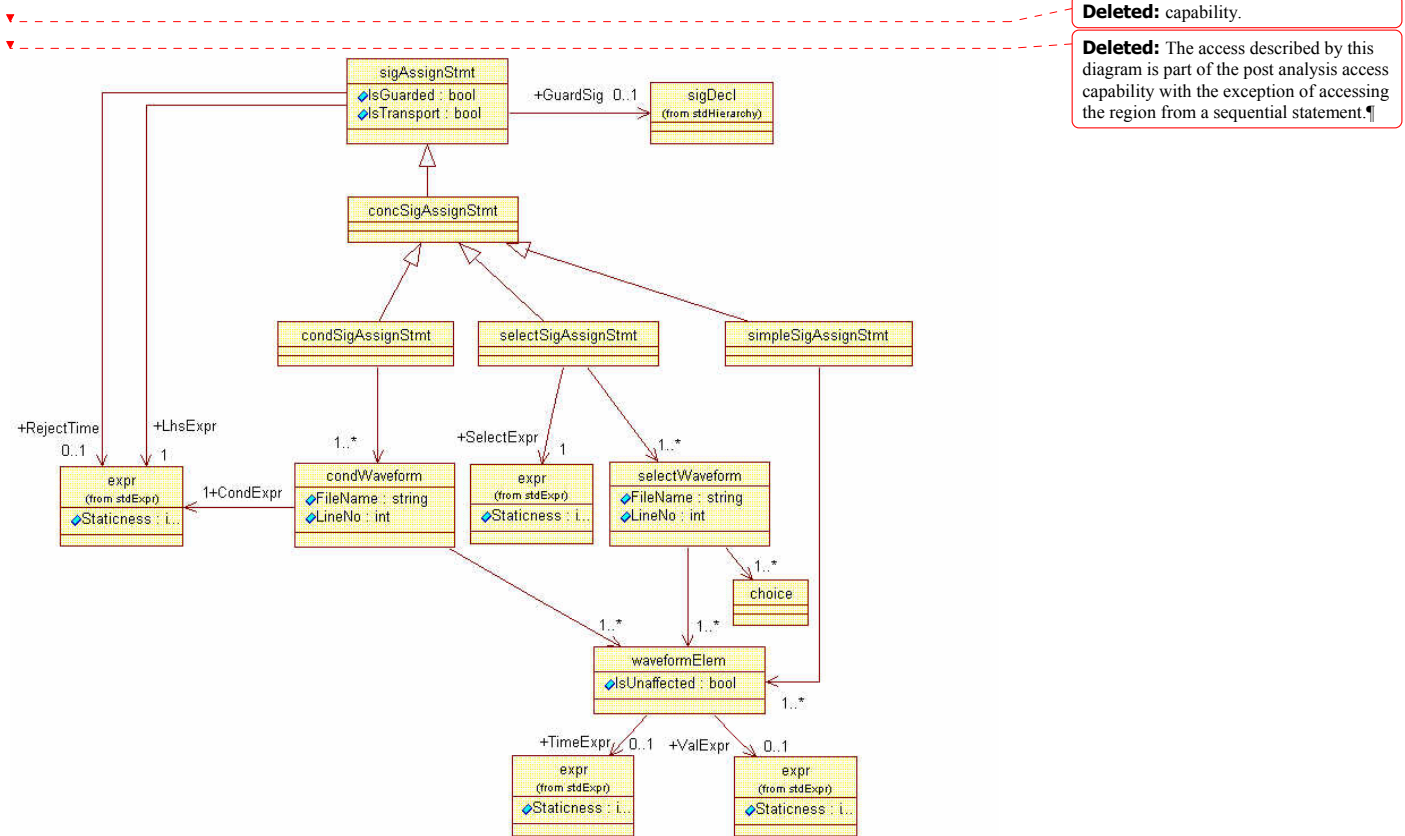

- 34. In the instantiated domain, if generate with condition expression evaluating to FALSE are not returned as handle. In the uninstantiated domain, all generate statements are returned. For example, iteration on stmts would return if generate with false condition.
- 35. In the instantiated domain a forGenerate handle is returned for each index. In the uninstantiated domain, a single forGenerate is returned.
- 36. The **vhpiCondExpr** relationship returns NULL if the ifGenerate is instantiated (**vhpiIsUninstantiatedP** property is FALSE) and an error is created. If the ifGenerate is uninstantiated, **vhpiCondExpr** returns a expression handle.
- 37. The **vhpiGenerateIndexP** property returns the generate index value if the forGenerate is instantiated; the property returns -1 and a error is created if the forGenerate is uninstantiated.

Formatted: Bullets and Numbering

1 | [38.](#) The relationships vhpiParamDecl and vhpConstraint are only available from an uninstantiated
2 | forGenerate handle.
3 | Issue uninstantiated/instantiated representation: decide if an error is created and if the relation ship should
4 | say 0..1
5 |

4.9.4 The concurrent signal assignments class diagram

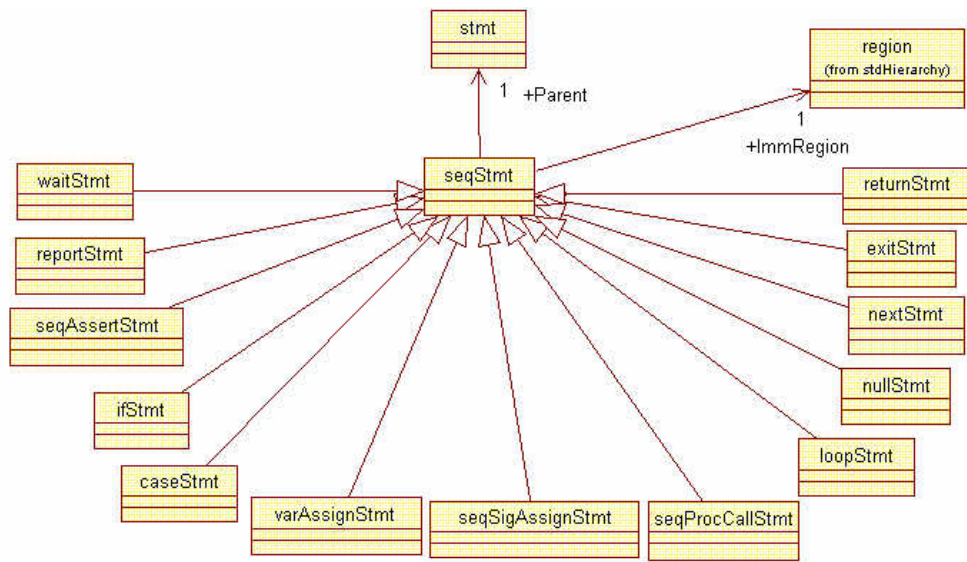

The access described is part of the static access and post analysis capabilities.

4.9.5 The sequential statement inheritance class diagram

The access described by this diagram is part of the static access capability.

The access described by this diagram is part of the post analysis access capability with the exception of accessing the region from a sequential statement.

1

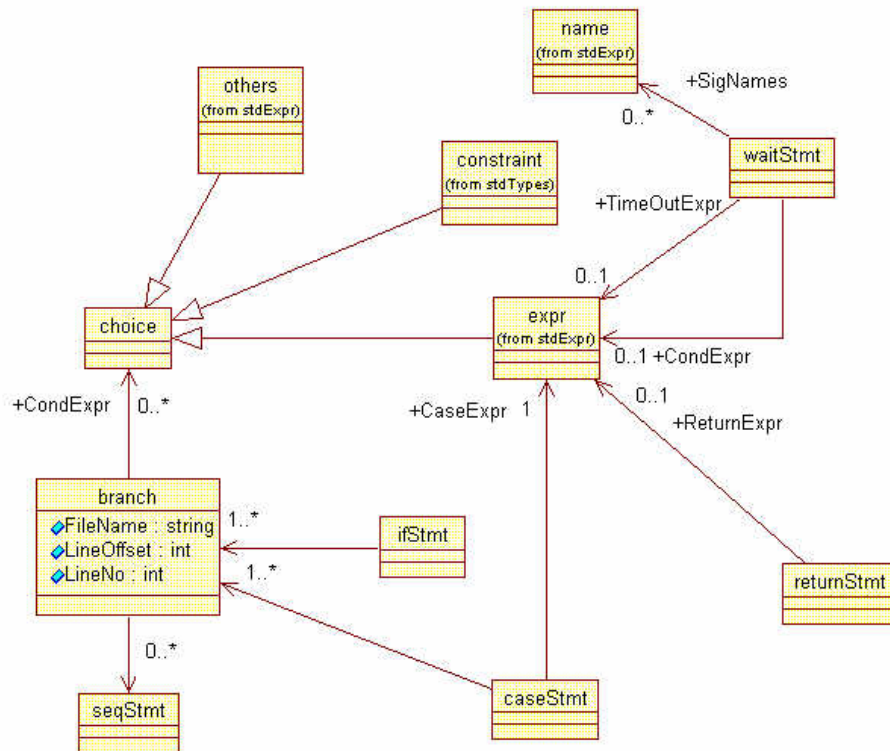

4.9.6 The sequential case, if, wait and return statement class diagram

The access described by this diagram is part of the static access and post analysis capabilities.

Notes:

- 39. how branches are returned for an ifStmt, the iteration on branch from the ifStmt class will return the branch of the if, then the branch of the elsif (if any) then the branch of the else (if any).
- 40. condExpr iteration from a branch of an ifStmt returns only one choice, condExpr from a caseStmt may return multiple choices.

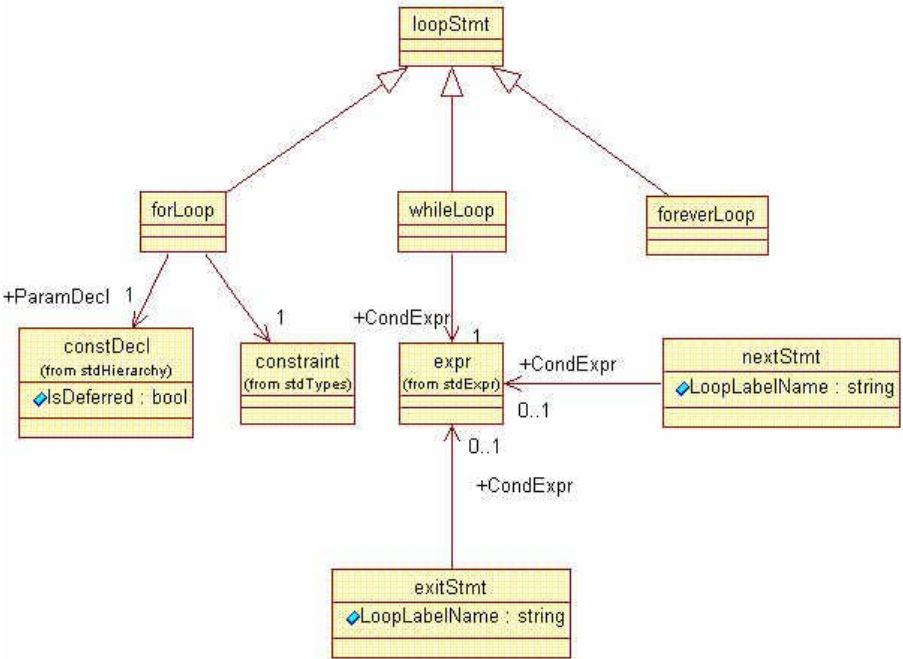

Formatted: Bullets and Numbering

19 The access described by this diagram is part of the static access and post analysis capabilities.
20
21

1

4.9.9 The signal assignment statement class diagram

The access described by this diagram is part of the static access and post analysis capabilities

Notes:

- 42. If the property **vhpiIsUnaffected** is TRUE, then **vhpiValExpr** and **vhpiTimeExpr** relationships shall return a null handle.
- 43. The VHDL expression was the null transaction if the **vhpiValExpr** return a null handle and the property **vhpiIsUnaffected** is FALSE.

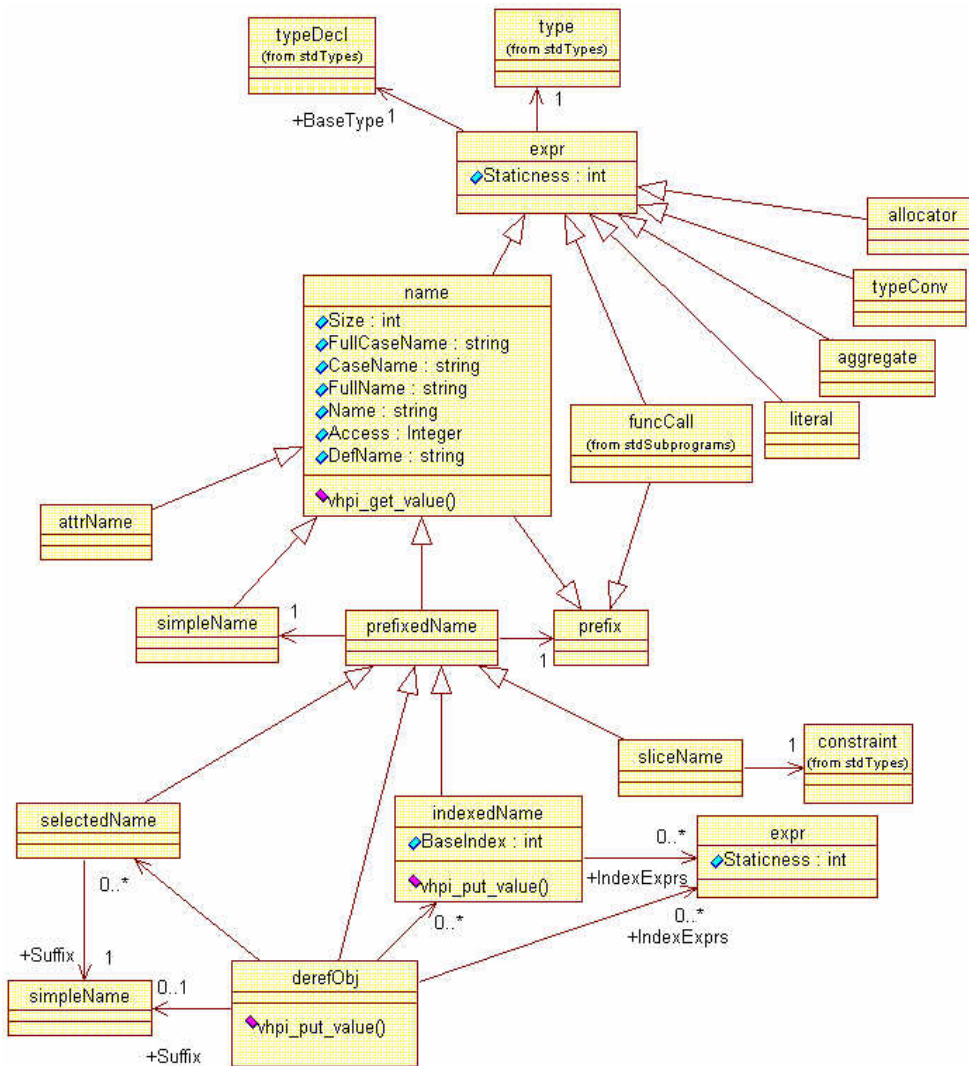

Formatted: Bullets and Numbering

4.10 The standard expression package

4.10.1 The expression inheritance diagram

The access described by this diagram is part of the static access and post analysis capabilities except for `vhpi_put_value` which is part of the debug and runtime and basic foreign capabilities. `vhpi_get_value` and `vhpi_put_value` of dereference objects is only part of the debug and runtime capabilities.

Issue: need to add access to `indexedNames` and `selectedNames` from a `derefObj`, do they return a `derefObj`?

Notes:

44. The iterations `vhpiSelectedNames` and `vhpiIndexedNames` are only available when the `vhpiDerefObjK` is instantiated. The relationships `vhpiSuffix`, `vhpiIndexExprs` and `vhpiPrefix` are only available when the `vhpiDerefObjK` is uninstantiated. `vhpi_put_value()` and `vhpi_get_value()` are only available when the `vhpiDerefObj` is instantiated.

Issue: should we say return NULL if instantiated? Do we generate an error or warning?

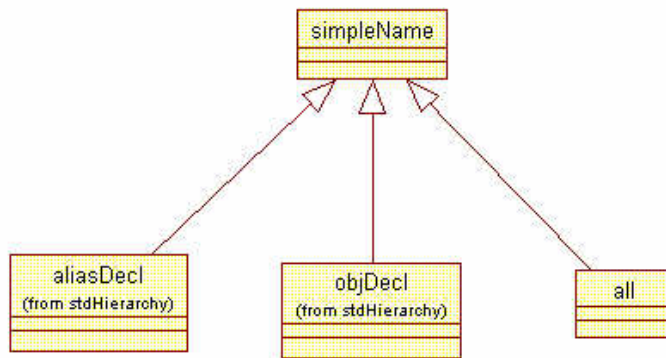

45. The `vhpiSuffix` relationship return the `simpleName` `vhpiAllK` when accessing the “all” suffix of a `vhpiDerefObjK`.

46. The `vhpiSelectedNameK` class represents only selected names of a record as all other VHDL selected names (package items selected names) have been resolved to their reference.

4.10.2 The simple name class diagram

The access described by this diagram is part of the static access and post analysis capabilities.

1

2

3 Note:

4 | 47. A simpleName is the vphiAllK class when denoting the all suffix of a uninstantiated vphiDerefObjK.

Formatted: Bullets and Numbering

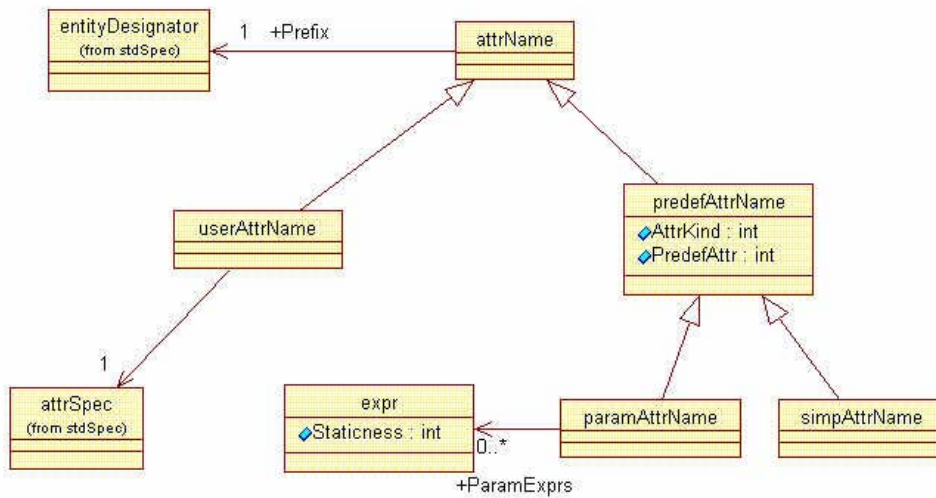

5

6 4.10.3 The attribute class diagram

7 The access described by this diagram is part of the static access and post analysis capabilities.

8

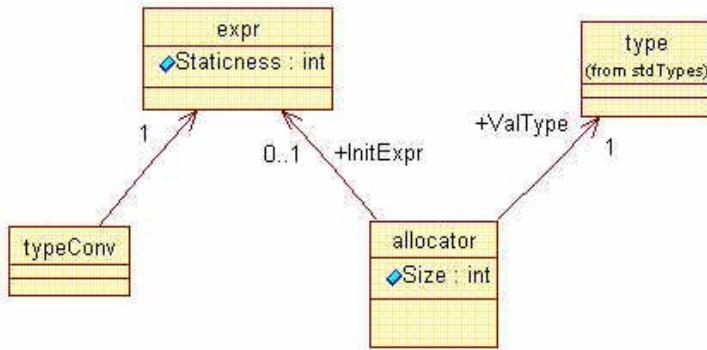

9

10

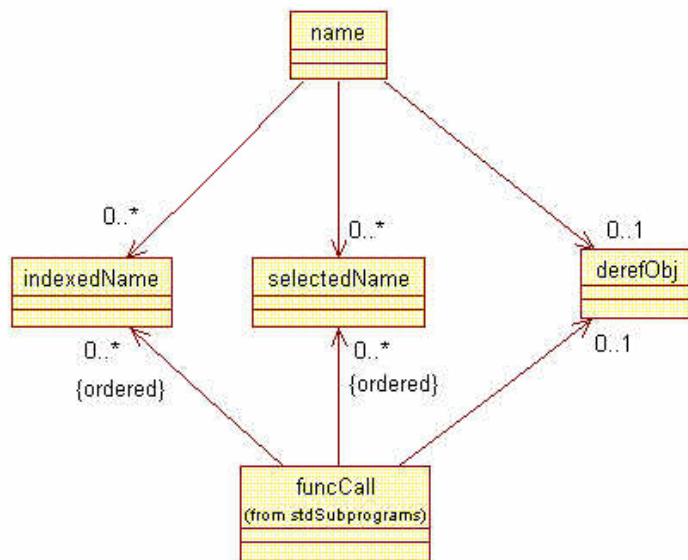

4.10.4 The type conversion, aggregate class diagram

The access described by these diagrams is part of the static access capability.
The access described by these diagrams is part of the post analysis access except for iteration on indexednames, selectednames which is part of the static access capability.
Access to the derefObj is only part of the debug and runtime capability.

4.10.5 The name access class diagram

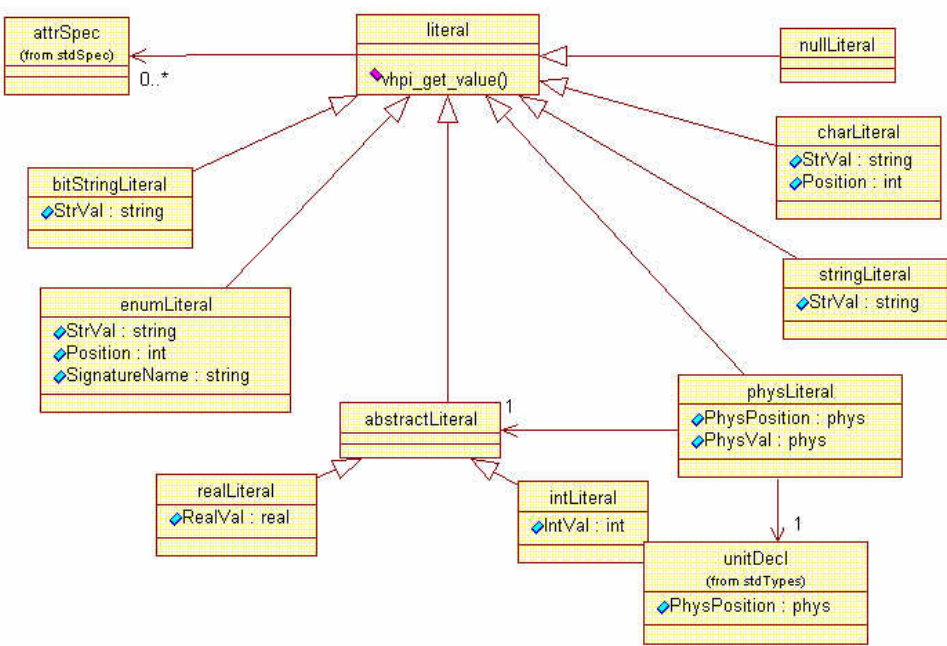

The access described by these diagrams is part of the static access capability.
The access described by these diagrams is part of the post analysis access except for iteration on indexednames, selectednames which is part of the static access capability.
Access to the derefObj is only part of the debug and runtime capability.
Access to indexedNames, selectedName and derefObj is part of the advanced foreign model capabilities.

1

1 4.10.6 The literal class diagram

5. Access to the Uninstantiated model

5.1 Scope

This document describes the functional specification for providing VHDL uninstantiated access, that is the VHPI model for accessing analyzed (non-elaborated) VHDL information. The access described in this chapter is part of the post analysis capability set.

In an analyzed VHDL model, the basic units are design units that reside in design libraries. A design unit is one of:

- 1) entity declaration
- 2) architecture body
- 3) package declaration
- 4) package body,
- 5) configuration declaration.

Access to an uninstantiated model is provided by referencing the library name and a design unit name.

The objective is to be able to recreate the VHDL source file (not necessary to preserve the same statement ordering as in the original source file). In particular, user should have access to component declarations, component instantiations, formals/actuals, unconstrained array types, configuration specifications, configuration body, etc... However, certain items processed during the analysis phase cannot be reverted back. Examples of some of these are locally constant expressions, comments...

Uninstantiated access is useful for tools that need access to the source VHDL via an API and do not need access to the hierarchy or connectivity information. Examples of such tools are: design rule checkers, coding style checkers and translators.

5.2 VHPI Application Contexts

VHPI supports two information models:

- the uninstantiated information model
- the instantiated information model.

Given the various phases of a tool:

vhpiCbStartOfTool -> vhpiCbStartOfAnalysis-> vhpiCbEndOfAnalysis->vhpiCbStartOfElaboration->vhpiCbEndOfElaboration->vhpiCbStartOfSimulation->vhpiCbEndOfSimulation->vhpiCbEndOfTool

The uninstantiated information model is available for access from vhpiCbStartOfTool till vhpiCbEndOfTool, while the instantiated information model is available for access from vhpiCbStartOfElaborationStart till vhpiCbEndOfTool. Specify that the tool capability must include vhpiProvidePostAnalysis.

Note: Library browsing can be done at CbStartOfTool.

Given a handle to an object in the uninstantiated information model, it is not possible to traverse a relationship to get to a handle of an instantiated object.

1 The reverse is not true, that is, there are cases where from the instantiated information model, you can
2 traverse a relationship to get to an object in the uninstantiated information model. Section 5.3.1 enumerates
3 all such cases.

4
5 For the instantiated information model, the context of operation for a VHPI application is the **elaborated**
6 **design context**. This context consists of:

- 7
8 - the entire elaborated design including the top-level package instances.

9
10
11 So a VHPI program can get access to the instantiated information model in one of two ways:

- 12
13 - by navigation from the NULL handle (get a handle to the root of the elaborated design, get
14 handles to package instances etc...)
- 15
16 - get a handle to an elaborated object via `vhpi_handle_by_name()`.

17
18 For the uninstantiated information model, a VHPI application only accesses uninstantiated information.

19
20 So a VHPI program can get access to the uninstantiated information model in one of four ways:

- 21
22
23 - get a handle to a library (working library or other design libraries).
- 24
25 - get a handle to an uninstantiated object via `vhpi_handle_by_name()`.
- 26
27 - navigate from the instantiated to the uninstantiated model (see section 5.8).

28
29 In this chapter, we describe the uninstantiated information model and access only.

30 **5.3 VHPI Uninstantiated Access**

31
32 The VHDL procedural interface is defined by:

33 the definition of a VHDL uninstantiated information model that represents the VHDL data that is
35 accessible by the procedural interface,

36
37 a subset of the functions that operate on this model to access, modify, and interact with the data.

38
39 The next sections define which subset of the VHPI information model is available, what additional new
40 information is available, and what are the functions that can legally be used in on the uninstantiated
41 information model.

42 **5.3.1 Uninstantiated Information Model**

43
44 During VHDL analysis, design units described in a design file are analyzed and each successful analysis
45 results in the analyzed design unit data being placed in a design library. The VHPI uninstantiated data is
46 the data resulting from the analysis of a design unit. A design unit is comprised of use clauses (dependent
47 analyzed units or declarations) and a single library unit which is either an entity, an architecture, a package,
48 package body or configuration declaration. Design units have only uninstantiated data. Any data obtained
49 by traversing a relationship from a design unit handle will lead to uninstantiated data. Any data obtained by
50 traversing a relationship from a reference handle of uninstantiated data gives back handles to uninstantiated
51 data.
52

From the uninstantiated information model, no access to the instantiated information model is allowed. Classes of objects which are not part of the uninstantiated information model are classes which denote elaborated or runtime data. For example, a handle of the region class can never be obtained in the uninstantiated model because it denotes an elaborated region instance.

It is possible to obtain a handle to uninstantiated data in the following cases:

- 1) When calling `vhpi_handle_by_name()` with the unit name of the design unit or with the string returned by the `vhpiDefNameP` property. The handle obtained is of class `vhpiEntityDeclK`, `vhpiArchBodyK`, `vhpiPackDeclK`, `vhpiPackBodyK`, `vhpiConfigDeclK` or a handle to uninstantiated data. Revisit after chapter 6 review.
- 2) When calling `vhpi_handle_by_name()` with the name of the library. Revisit after chapter 6 review
- 3) When traversing a relationship from a handle of uninstantiated data.
- 4) When applying the 1-to-many relationship `vhpiLibraries` to a NULL reference handle; this will yield all the libraries made available to the tool.
`vhpi_iterate (vhpiLibraryDecls, NULL)`
(The association of the physical library to the logical library is tool-specific).
- 5) When traversing a specific relationship from the instantiated information model. This set of relationships is defined later in the document.

In the uninstantiated information model, it is not possible to access information which pertain to elaboration, connectivity or runtime. In addition, only handles to objects which have an existing reference in the VHDL description can be obtained. For example it is not possible to iterate on `vhpiIndexedNames` from a handle of a variable declaration which is of an array type.

5.3.2 New additions

5.3.2.1 Lexical Scope Class

Given a handle to an uninstantiated declaration, the 1-to-1 method `vhpiLexicalScope` will return a handle to the enclosing lexical scope of that declaration. The lexical scope relationship will return NULL for a reference handle denoting a library declaration.

The lexical scope relationship returns a handle of the lexical scope class which is one of the following classes:

- sub-classes of the design unit class: `vhpiEntityDeclK`, `vhpiArchBodyK`, `vhpiPackDeclK`, `vhpiPackBodyK`, `vhpiConfigDeclK`
- some sub-classes of the class `decl`: `vhpiFuncDeclK`, `vhpiProcDeclK`, `vhpiProtectedTypeDeclK`, `vhpiProtectedbodyK`, `vhpiCompDeclK`, `vhpiRecordTypeDeclK`,
- some sub-classes of the class `stmt`: `vhpiBlockStmtK`, `vhpiLoopStmtK`, `vhpiForGenerateStmtK`,
- a class of kind `vhpiBlockConfigK`, `vhpiCompConfigK`

The `vhpiLexicalScope` class is only valid in the uninstantiated information model with a reference handle to an uninstantiated declaration. Following is the class diagram for the lexical scope class:

1 Lexical Scope class diagram (see diagram 4.4.2)

3 5.3.3 Expanded Names

4 Move this to the name class diagram.

5 In a VHDL source file, there may exist a number of out-of-scope references, called **expanded names**.

6 Examples of these are:

```
7 IEEE.NUMERIC_BIT.UNSIGNED
8 WORK.ALU(RTL)
9 MY_PACK.SIG_A
```

10
11 VHPI does not provide full information about expanded names references. This has the drawback to not
12 being able for decompilation applications to exactly produce the original source. This is more efficient for
13 synthesis oriented applications and more inline with the information retained by analyzers.

14 5.3.4 Unsupported classes

15
16 The following **class kinds** of vhpi handles are not supported in the uninstantiated information model:

```
17  
18 vhpiDriverK,  
19 vhpiDriverCollectionK,  
20 vhpiForeignfK,  
21 vhpiInPortK,  
22 vhpiOutPortK,  
23 vhpiPackInstK,  
24 vhpiProtectedTypeK,  
25 vhpiRootInstK,  
26 vhpiTransactionK.
```

27 5.3.5 Unsupported 1-to-1 relationships

28 The following **1-to-1 relationships** are not valid in the uninstantiated information model:

29 Issue: missing association from the forGenerate and ifGenerate classes

```
30 vhpiBasicSignal,  
31 vhpiContributor,  
32 vhpiCurCallBack  
33 vhpiCurEqProcess,  
34 vhpiCurStackFrame,  
35 vhpiDerefObj,  
36 vhpiDownStack,  
37 vhpiImmRegion,  
38 vhpiInPort,  
39 vhpiOutPort,  
40 vhpiProtectedTypeBody,  
41 vhpiRootInst,  
42 vhpiUpStack,
```

vhpiUpperRegion.

5.3.6 Unsupported 1-to-many relationships

The following **1-to-many relationships** are not valid in the uninstantiated information model:

vhpiBasicSignals,
vhpiContributors,
vhpiCurRegion,
vhpiDrivenSigs,
vhpiDrivers,
vhpiForeignfs,
vhpiIndexedNames,
vhpiInternalRegions,
vhpiPackInsts,
vhpiSelectedNames,
vhpiSigAttrs,
vhpiTransactions.

Deleted: s

Deleted: Issue I019
(curEqProcess)

A vhpi error will be generated if the functions `vhpi_handle()` and `vhpi_iterator()` are used for a uninstantiated handle and the iteration method or the 1-to-1 method is one of the invalid methods listed above. In these cases, the functions will return a null handle. The vhpi error can be checked immediately after the call to `vhpi_handle()` and `vhpi_iterator()` by calling `vhpi_check_error()`.

5.3.7 Unsupported integer properties

The following **integer properties** are not valid in the uninstantiated information model:

vhpiAccessP, (read, write, or no access at all)
vhpiForeignKindP,
vhpiFrameLevelP,
vhpiGenerateIndexP,
vhpiIsBasicP,
vhpiIsDefaultP, (binding of the component
instance is default binding)
vhpiIsForcedP,
vhpiIsForeignP,
vhpiIsOpenP,
,
vhpiLoopIndexP,
vhpiResolutionLimitP.

A vhpi error will be generated if the functions `vhpi_get()` and `vhpi_get_str()` are used with an integer /string property which is invalid in uninstantiated mode. The function `vhpi_get()` will return an unspecified value and `vhpi_get_str()` will return null. The vhpi error can be checked immediately after the call to `vhpi_get()` or `vhpi_get_str()` to check for error by calling `vhpi_check_error()`.

5.3.8 Unsupported functions

The following vhpi functions are not valid in the uninstantiated information model:

```

1
2           - vhpi_protected_call
3
4           Value access and modifications:
5           - vhpi_get_value : will only returns values
6             for locally static expressions
7           - vhpi_put_value
8           - vhpi_schedule_transaction
9
10          Simulation access and control function:
11          - vhpi_get_time
12          - vhpi_control
13          - vhpi_put_data
14
15          Foreign function registration:
16
17          - vhpi_register_foreignf
18          - vhpi_get_foreign_info
19
20 Notes:
21 1. vhpi_handle_by_index (invalid when creating a handle to an indexedName or selectedName because the
22 iterations on indexedNames and selectedNames are illegal in uninstantiated access).
23 2. Callback functions:
24 - vhpi_register_cb
25 - vhpi_disable_cb,
26 - vhpi_enable_cb,
27 - vhpi_get_cb_info,
28 (Action callbacks are allowed, object and stmt callbacks cannot have uninstantiated handles. Time
29 callbacks are not allowed...).
30 3. vhpi_create is not allowed to create a driver or a processStmt handle.
31
32 The use of functions which are not supported in the uninstantiated model will generate a runtime vhpi error.
33 The functions which return a handle or a status code will respectively return a null handle or the code for
34 failure.

```

35 5.3.9 vhpi_handle_by_name

36
37 See section 6.2

38 5.3.10 Instantiated to uninstantiated model

39 Issue: mark these associations in the information model.
40 Issue: add associations from the information model which return uninstantiated handles.
41
42 This section lists the list of legal relationships that can be used to cross from the instantiated information
43 model to the uninstantiated information model:
44

- 45 1) vhpiCompInstStmtK to designUnit class
- 46 2) vhpiRootInstK to vhpiConfigDeclK
- 47 3) vhpiCompInstStmtK to vhpiConfigSpecK

- 1 4) vhpiCompInstStmtK to vhpiCompDeclK
- 2 5) vhpi_handle_by_name passing the string of the vhpiDefNameP
- 3 property
- 4 6) subprogram
- 5 7) forloop

6 No other accesses shall be allowed.

7 5.3.11 Additional Comments

8
9

10 When iterating on statements in the uninstantiated model, you get handle to an if generate statement even if
11 the conditional expression is locally static (and false). On the contrary, in the instantiated model, an
12 ifGenerate statement whose condition is false will not be returned since it has not been elaborated.

13
14

15 6. VHPI names properties, Access by name lookup

16

17 Move this paragraph as an introduction to chapters 4, 5, 6

18 VHPI provides two related but distinct formal information models. The instantiated design model is an
19 instance hierarchy, i.e., the root instance, its component and block instance hierarchy, etc., that results from
20 elaboration of a VHDL design. The uninstantiated information model is a library of design units
21 previously analyzed. The relationship between them is that during the elaboration phase, the analyzed
22 design units are instantiated into the instance hierarchy. After elaboration, instances in this hierarchy have
23 a relationship back to corresponding design units in a library; the structure and behaviour of an instance are
24 defined by the design units to which they are bound. If a VHPI tool claims to support post analysis
25 capability, it supports access to the uninstantiated information model.

26

27 Many object classes in each information model have name properties, strings that convey naming
28 information to VHPI client applications. These are useful in referring to these objects in written output in
29 terms the end user can relate back to the original VHDL source.

30

31 VHPI clients have a variety of mechanisms to obtain handles to objects in either information model. From
32 an initial handle, one may navigate to other handles. Alternatively, one may search for a handle by name.
33 The search string may be an absolute or relative path name. A search may be limited to a specific region or
34 design unit

35

36 The next section identifies the name properties available in both the library and design information models.
37 After that, vhpi_handle_by_name functionality is defined. Open issues are identified and rationale
38 included, as appropriate.

39 6.1 VHPI Name String Properties

40

41 The name string properties can be understood by examining the UML formal information model and using
42 the definitions below. Both the instantiated and ~~library~~ information model objects share some name
43 properties. To avoid confusion, their descriptions are repeated.

44 Issue: replace uninstantiated with library unit and instantiated with design hierarchy

Deleted: uninstantiated

6.1.1 Name Properties - Instantiated Information Model (design hierarchy access)

The instantiated information model includes everything that is constructed during VHDL elaboration phase and can be broadly divided into the design instance hierarchy and the elaborated packages referenced by the design.

With respect to the UML of the design model, the named objects are primarily regions (see the region inheritance class diagram) and decls (see the declaration class diagram).

6.1.1.1 vhpiNameP

This property returns the name of the designated object in unspecified case for basic identifiers (VHDL is case insensitive) or case preserved for extended identifiers. Broken down by class:

6.1.1.1.1 decl - for a declared item, its identifier

The vhpiNameP of a declaration is the declaration identifier name. The vhpiNameP of a subprogram declaration (vhpiSubpDeclK) or subprogram body (vhpiSubpBodyK) is the subprogram identifier name. The vhpiNameP of a vhpiLibraryDeclP is the library logical name.

Issue: This is *not* equivalent to the 'simple_name predefined attribute. For example, 'simple_name is guaranteed to return all lower case. Resolution : A name property equivalent to vhpiSimpleNameP was not determined necessary.

Note: since an enumeration literal *or subprogram* can be overloaded, *a property vhpiSignatureNameP can return the parameter type profile string of the enumeration literal or subprogram. The vhpiNameP property of an enumeration literal or subprogram shall return the simple name of the enumeration literal or subprogram. For example for a enumeration literal named red and belonging to the enumeration type "color_type", the vhpiNameP property shall return "red" and the vhpiSignatureNameP shall return "return color_type" in order to distinguish it from another enumeration literal of the same name belonging to another enumeration type.*

Issue: vhpiNameP property can be queried on a handle of an implicit declaration and returns the declaration name.

For example, guard signals have a simple name of "GUARD". These can be found with vhpi_handle_by_name.

The name property applied to implicitly defined operators (for example "+" from the the standard package) follow the syntax for overloaded functions. The vhpiNameP of an operator declaration should include the double quotes.

6.1.1.1.2 complInstStmt – its instance label

For a vhpiCompInstStmtK reference handle, the vhpiNameP property returns the component instance statement label.

6.1.1.1.3 rootInst – the entity name

For a vhpiRootInstK reference handle, the vhpiNameP property returns the entity name (it was agreed for mixed language interoperability verilog returns the name of the top level module)

6.1.1.1.4 packInst - its package name

6.1.1.1.5 blockStmt - the block label

6.1.1.1.6 loopStmt – the loop label or an implicitly created label

<vhpiFullNameP of upperRegion>:<vhpiNameP of loopStmt>

Deleted: t

Deleted: should be

Deleted: [

Deleted:]

Deleted: This is consistent with the syntax for an overloaded parameterless function whose return type is color_type (see section 5.2.1.11). This is how the VHDL LRM describes enumeration literals.¶

Deleted: Add vhpiSignatureNameP property for vhpiSubpDecl and vhpiEnumLiteralK ; reconcile with vhpiFullName¶

Deleted: (reconcile with signatureName)

1 See Rule 1 below for generating implicit loopStmt labels.
 2 Because the loop stmt variable is dynamically elaborated, it is advanced functionality. If the VHPI server
 3 conforms to “dynamically elaborated” capability, handles to loop variables may be obtained (See section
 4 1.1.2 VHPI levels of capability). The vhpNameP property of a loop variable would be its identifier.

5 6.1.1.1.7 generateStmt - the <label_name>[(generate index)]

6 There are two forms of generate, a conditional generate and an iterative generate. For a conditional
 7 generate, the vhpNameP is the label name. With an iterative generate stmt, each iteration replicates the
 8 contents of the generate stmt, i.e., generates a block instance of its declarations and concurrent stmts. The
 9 generate_index is the value of the for generate constant that defines the iteration. This implicit constant
 10 declaration is defined with a discrete range, either an integer or enumerated type. For the purpose of the
 11 vhpNameP string, the value of the generate_parameter of an enumerated type will be given by the string
 12 representation of the enumeration literal.

13 6.1.1.1.8 VHDL name

14 IndexedName, SelectedName, SliceName, derefObj, ParamAttrName, SimpAttrName, UserAttrName,
 15 (see name class diagram) the VHDL string name equivalent to the object the name refers to.
 16 It may not be returned as it appears in the VHDL source because a single handle may represent expressions
 17 of the same object.

18 Example: s(1), s(1 + 0), s(c) where C is the integer constant 1, may have the same vhpNameP of “s(1)”

19
 20 The name may be returned with or without case preserved depending if there is reference to an extended
 21 identifier within the name.

22
 23 Example: selected name: “f.a”, indexed name: “r(j)”, “a.all”, “s’delayed”, “t’high”, “my_attribute”, etc...

24
 25 Note: a vhpDerefObjK handle will only have a name if it refers to a VHDL source dereference name.
 26 vhpDerefObj handles which are obtained by way of applying the vhpDerefObj method do not have a
 27 name because they denote a memory location in the VHDL heap.

28 6.1.1.1.9 EqProcessStmt – the process label or implicitly generated label

29 See Rule 2 below for generating EqProcessStmt labels. An equivalent process statement is either a process
 30 statement or one of the concurrent statements - procedure call, assertion, or signal assignment.

31 6.1.1.1.10 protectedType

32
 33 A vhpProtectedTypeK handle represents the instantiated variable of a protected type. The vhpNameP of a
 34 vhpProtectedTypeK handle is the name of the variable. The vhpNameP of protected type declaration
 35 vhpProtectedTypeDeclK or vhpProtectedTypeBodyK is the protected type identifier name

36 6.1.1.1.11 subpCall and stackFrames

37 a) name of a procedure call stmt:

38 When the procedure call statement is executed, a stack frame is created which represents the state of the
 39 procedure call. ~~For a concurrent procedure call, the vhpNameP property shall return the explicit or~~

40 ~~automatically generated name of the equivalent process representing the concurrent subpcall.~~

41 ~~For a sequential procedure call the vhpNameP property shall return name of the of the subprogram. The~~
 42 ~~vhpNameP property returns the same strig value whether or not the procedure is active.~~

43 ~~There is a special case when the procedure call denotes a method of a shared variable of a protected type;~~
 44 ~~in that case the vhpNameP of the procedural call or function call should be:~~

45 <variable_name>.<vhpNameP of the subpCall>

46 When an object of a protected type is used in VHDL, it is accessed through protected procedure and
 47 function calls. Its name is defined consistently with subpCall objects. The procedure call name is

48 <variable_name>.<subp_name>().

Deleted: T

Deleted: of a subpCall should be the

Deleted: concurrent or sequential

Deleted: When the procedure call is not
executing, the vhpNameP should
return the procedure declaration name.

Deleted: ¶

We should provide handles to concurrent procedure calls when traversing hierarchy. Access to concurrent procedure calls should not be restricted by the VHPI server. ~~Concurrent~~ procedure calls are transformed in their equivalent processes with sequential procedure calls. Dynamic elaboration applies to sequential procedure calls.

Deleted: I sent out an email to Paul and Alex asking if the dynamic elaboration was applying to concurrent procedure calls.
Paul replied that concurrent

b) name of a function call

A function call is an expression.

The `vhpiNameP` of a function call is the name of the function declaration. Ex: "my_func". In the case of a function call applied to a shared variable of a protected type, the name should include the shared variable name:

Deleted: ¶

Deleted: ¶

6.1.1.2 `vhpiSignatureNameP`

This property is available for `subpCall` and `enumLiteral`.

The property returns a string which represent the signature of the `subpCall` or enumeration literal. An enumeration literal is represented as a parameterless function call.

Deleted: `<variable_name>.<vhpiNameP of the subpCall>`

```
[[<vhpiNameP of parameter type declaration>]{, <vhpiNameP of parameter type declaration>}]return  
<vhpiNameP of return type>]]
```

6.1.1.2.1 Rule 1 - Naming of unlabelled loop statements:

VHPI would generate a loop label which starts by the concatenation of the "_L" or "_I" string and an integer which denotes the sequence appearance number of the loop statement in the VHDL source text of the declared region. The numbering starts at 0 and increments by 1. For example the auto-generated `vhpiNameP` of the first loop statement in process or postponed process would be "_L0". Numbering of loops is reset for each internal region.

Rationale: A loop variable is an important object to access by name. Because the label is optional, 'path_name' attribute can be ambiguous. The `vhpiNameP` property must produce reliable names that are unique references to an object to support `handle_by_name`. Because the loop variable is dynamically elaborated, look up by name of the loop variable is advanced functionality. The fullname of the loop variable would include the process label, the explicit or automatically generated loop label and the loop variable.

Example:

"Process_label:loop_label:loop_var"

6.1.1.2.2 Rule 2 - Naming of unlabelled equivalent processes:

VHPI would generate an equivalent process label name which starts with the concatenation of the "_P" or "_p" string and an integer which denotes the sequence appearance number of the equivalent process in the VHDL source text of the declared region. The numbering starts at 0 and increments by 1. For example the auto-generated `vhpiNameP` of the first equivalent process statement in an entity declaration would be "_p0". Numbering of equivalent processes in the architecture follows the numbering sequence used for the entity. The number used for the first process in the architecture will be either 0 if the entity did not contain any unlabelled processes or n+1 where n is the number used for naming the last unlabelled equivalent process of the entity. Numbering of processes is reset for each internal region (block, generate or component statement).

example: "_P2" is the `vhpiNameP` of the second occurring process for this entity/architecture pair.

note: `_P2` is not a legal VHDL identifier (should be escaped) this ensures that this identifier is not used in the rest of the design.

Rationale: Because the label is optional, 'path_name' attribute can be ambiguous. The `vhpiNameP` property must produce reliable names that are unique references to an object to support `vhpi_handle_by_name`.

6.1.1.3 vhpiCaseNameP

Returns the case preserved name of the declared identifier.

I propose that vhpiNameP of implicit declarations returns the implicit declaration identifier (for example for the guard signal, the operator name for an implicit operator etc... vhpiCaseNameP would return the same as vhpiNameP for implicit declarations.

In the case of:

- a declaration appearing in both the subprogram declaration and its body,
- a subprogram declaration and its subprogram body,
- an incomplete type and its full type,
- a protectedTypeDeclaration and its body,
- a package declaration and its body,

the vhpiCaseNameP shall return the case preserved name of the declaration in the subprogram declaration, the incomplete type, the protectedType declaration or a package declaration.

Issue: check rational + specify new compliance capability for names

Deleted: ,

6.1.1.4 vhpiFullNameP

This is a string describing the path through the elaborated design hierarchy, from the top level entity or package to this object. The string is defined in terms of the vhpiNameP property to produce a unique reference to the given object. Objects which have the vhpiFullNameP property are explicit declarations, sub-elements of these declared objects, or regions.

The vhpiFullNameP property returns a string that is often identical to X'PATH_NAME attribute, but will differ because of ambiguities and features of the inherent in the VHDL LRM definition.

Since VHDL is case insensitive, the case of the vhpiFullNameP string is not specified unless there is an extended identifier.

Note: vhpiFullCaseNameP should be used to retrieve the hierarchical name with case preserved characters for the declared items only.

6.1.1.4.1 Elaborated design object :{<vhpiNameP>}[vhpiNameP]

The vhpiFullNameP property should return the concatenation of the vhpiNameP strings of each instance or item found on the hierarchy path. The character ':' is used between two successive names returned by vhpiNameP.

The vhpiFullNameP of an object declared in a subprogram would only be obtainable if the subprogram is elaborated and consequently the object is elaborated too. Therefore the fullName of that object would contain the vhpiNameP of the subprogram call as defined above.

Ex: The vhpiFullNameP of a variable A defined as a subprogram parameter, elaborated as part a concurrent subprogram call, would be:

<vhpiFullNameP of the base eqProcessStmt representing the concProcCallStmt>:A

The fullname of an to uninstantiated declarations is equivalent to the vhpiDefNameP (fullname in the library information model).

The vhpiFullNameP of the root instance is ";<entity_name>. This is sufficient to refer to a unique root, VHDL 1993 and 2000 only allow one top-level design unit This brings it inline with 'path_name'. It is also the only way to deal with the stated goal of interoperability with Verilog and VHDL.

Deleted: For

Deleted: its full name

Deleted: <vhpiNameP of subpCall

Deleted: Issue: reconcile with

Deleted: applied

Deleted: => A declared item in a function declaration does not have a fullname as it is not elaborated¶

6.1.1.4.2 Library declaration

The vhpiFullNameP of a vhpiLibraryDecl is: @<lib_logical_name>

6.1.1.4.3 Elaborated package object @<lib_logical_name>:<pack_name>[vhpiNameP]

The `vhpiFullName` for an object in an elaborated package instance returns a string that is nearly identical to the ``path_name` attribute, but differs in order to resolve ambiguities in the VHDL LRM definition. The leading `:` is replaced with an `'@'` character to disambiguate a name reference to an elaborated design object from a reference to a package object with the same name. For example, “work” can be both a logical library name and the entity name of the design root.

Construction of full names for items elaborated in package instances is defined as follow:

`@<lib_logical_name>:<pack_name>:<vhpiNameP of declared_item>`

The `declared_item_name` is equivalent to the `vhpiNameP` property of the declared object.

6.1.1.4.4 subpCall

`<vhpiFullNameP of upperRegion of base eqprocess stmt>:<vhpiNameP of subpCall>{<vhpiNameP of subpCall>}`

This would work for both concurrent and sequential procedure calls.

For concurrent procedure calls, the names would reduce to the name of the `eqprocessstmt` it corresponds to. For sequential procedure calls, the name would be formed of the name of the enclosing `eqprocessstmt`, to which would be appended the `vhpiNameP` of the procedure.

6.1.1.4.5 vhpiPathNameP

Rationale: provides an ability to write foreign models and application output consistent with the simulator. This is a string describing the path through the elaborated design hierarchy, from the top level entity or package to this object. The `vhpiPathNameP` is identical to the VHDL predefined attribute, ``path_name`, as defined in the LRM 1076. A VHPI tool should guarantee that the same value will be used for ``path_name` attribute during simulation.

6.1.1.4.6 vhpiInstanceNameP

The `vhpiInstanceNameP` is identical to the VHDL predefined attribute, ``instance_name`, as defined in the LRM 1076. This is a string similar to ``path_name`, but includes the names of the entity and architecture bound to each component instance in the path. (Same rational as 5.1.1.3.3).

6.1.1.4.7 vhpiCaseNameP

This property returns the case preserved string of the item declaration. The string returned will reflect lower or upper case characters used in the identifier declaration. Note that for extended identifiers, or unlabelled loop statements or equivalent processes, the `vhpiCaseNameP` string will be exactly the same as the `vhpiNameP` string.

6.1.1.4.8 vhpiFullCaseNameP

The string returned is formed by the concatenation of each single `vhpiCaseNameP` string on the hierarchical path to the designated object. The `'.'` character is the delimiter between each simple case name.

Note: All these properties `vhpiNameP`, `vhpiCaseNameP`, `vhpiFullNameP` and `vhpiFullCaseNameP` apply to the name class (see expression diagram) and region class.

6.1.1.4.9 vhpiDefNameP

This property returns the full name of the associated object in the uninstantiated information model; this property is available for all objects which have a name.

`vhpiDefNameP` syntax use `.` separator and is defined in terms of `vhpiUnitNameP`,

Note: This property is available in both the elaborated model and uninstantiated model.

6.1.1.4.10 vhpiUnitNameP

This property is available in both the elaborated model and uninstantiated model. See uninstantiated model properties for description.

6.1.1.4.11 vhpiFileNameP

This property returns the physical file system path name of the VHDL source file where the item designated by the handle appears. This property is applicable for every VHPI class kind that has a vhpiLineNoP (line number property). Among these are: declared items, design units, etc...
Note: the VHPI specification does not imply the physical organization of a file system and makes no normative reference to file system specifications.

6.1.1.5 Name Properties - Uninstantiated Information Model (Library unit access)

The uninstantiated information model is a library of previously analyzed design units related to the current execution of the underlying tool providing VHPI. During the elaboration phase, some of these analyzed design units are instantiated into the hierarchy. After elaboration, instances in the design hierarchy have a relationship to design units in a library, they are defined by them (see design unit class diagram 4.4.1).

6.1.1.6 The uninstantiated model

The UML diagrams shares object classes between the uninstantiated and instantiated model, but these object classes are understood to have differences. See chapter on uninstantiated access to understand these differences. Issue: How do we represent this in UML?
The design unit class in the unelaborated data model is unique and has a number of unique properties. There are no regions in the instantiated model, but rather lexical scopes which affect some of the name properties.

6.1.1.7 vhpiLibLogicalNameP - the logical name of the library in which the design unit was compiled

This property returns the logical name of the library in which the design unit was analyzed.

6.1.1.8 vhpiLibPhysicalNameP - the physical name of the library

No interpretation implied by VHPI since that mapping is a tool issue, not an LRM issue.

6.1.1.9 vhpiUnitNameP: for design unit class

The name of the declared design unit in the VHDL source. This property is only applicable to the designUnit class. The separator is the . character.
The name is returned in unspecified case for basic identifiers or case preserved for extended identifiers. The vhpiUnitNameP of a design unit of the following class is:

EntityDecl: lib_name.entity_name
Arch body: lib_name.entity_name:arch_name
PackDecl: lib_name.pack_name
Pack Body: lib_name.pack_name:BODY
note: all variations of upper and lower case letters for BODY are allowed.
Config: lib_name.config_name

This property is allowed in the instantiated and uninstantiated design.

6.1.1.10 vhpiNameP – exists for declaration and name class and should produce the same string as in the elaborated model.

The string returned conforms to and is the same as the string returned in the instantiated model with the following exceptions:
For forGenerate, the vhpiNameP string returns the label without the index.

For non locally static names, the vhpiNameP string may return a name that is different from the name in the elaborated model. For example, the vhpiNameP of an indexedname when the index is globally static may be S(gen) in the analyzed model but S(0) in the elaborated model.

6.1.1.11 vhpiFullNameP, vhpiDefNameP syntax:

@<vhpiUnitNameP>{.<vhpiNameP of the
vhpiLexicalScope>}.<vhpiNameP>]

The vhpiFullNameP of an uninstantiated handle is identical to the string which would be returned by vhpiDefNameP. This is a string describing the path through the analyzed design unit, from the library through lexical scopes to this object. The string is defined in terms of the other properties to produce clear, unique references to the object.

6.1.1.12 vhpiCaseNameP no change

6.1.1.13 vhpiDefCaseNameP – analogous to vhpiDefNameP but case preserved

6.1.1.14 vhpiFileNameP – no change

6.1.2 Other Name Properties

Other string properties are defined:

6.1.2.1 vhpiCompNameP for complnstStmt, compConfig

vhpiCompNameP returns the component name specified for a component instance statement or component configuration or null if direct instantiation is used.

6.1.2.2 vhpiComplnstNameP for vhpiComplnstStmtK

Returns the string written in VHDL of either the configuration name, component name or entity architecture name. The name string includes the library name either explicit or default.

Deleted: Francoise to complete:

6.1.2.3 vhpiLabelNameP for the stmt class

returns the label name if it exists for the statement or null.

6.1.2.4 vhpiLoopLabelNameP for vhpiNextStmtK and vhpiExitStmtK

This property returns the label name of which to jump to or to exit from if the next or exit statement have an explicit label; null otherwise

6.1.2.5 vhpiLogicalNameP for vhpiFileDeclK class

This property returns the logical name which identifies an external file in the host file system which is associated with the file declaration; otherwise null

6.2 Access by name lookup

The goal is to define vhpi_handle by name in terms of name string properties for consistency in user interface input and output. The name properties have a clear definition in both information models. VHPI

provides `vhpi_handle_by_name` function to obtain a handle to an object in either the instantiated or uninstantiated information models. The latter capability is referred to as the post analysis capability in section 1.1.2 for compliance. `vhpi_handle_by_name` is only allowed on classes of objects which possess the `vhpiFullNameP` property. If a compliance capability requires access to a given class which has the `vhpiFullNameP` property, it is also required that `vhpi_handle_by_name` be supported as well.

The `vhpi_handle_by_name` function uses a case insensitive comparison of the search string to the `vhpiFullNameP` value, except where a component of the name uses extended identifiers. That component of the name will be compared with case sensitivity.

It may be possible to specify a name string that is ambiguous, i.e., that refers to more than one object. If `vhpi_handle_by_name` detects ambiguity, it will return a NULL handle. If this is not detected, the object handle returned will be the arbitrary choice of one such object. VHPI does not require detection of this condition.

Implicit signal attributes cannot be returned by `handle_by_name`. In order to find the signal attributes implicitly defined by a design on a given signal, use the `vhpiSigAttrs` iteration relationship.

6.2.1 Instantiated Model Access(Design hierarchy)

The interface provides a `vhpi_handle_by_name` function, which given a reference scope handle and an instantiated hierarchical name which identifies a given VHDL item, returns a handle to the designated item if an item of that name exists in that scope. This function (`vhpi_handle_by_name()`) can only be used for VHPI classes that possess the `vhpiFullNameP` property.

A scope reference handle of NULL denotes the top level of the design. The reference handle can be any of the packages instances or root instance of the design hierarchy or any region handle in the entire design. Any other type of handle to an instantiated model object is an illegal scope reference.

The `vhpiFullNameP` property is similar to the VHDL ``path_name` attribute, but has been extended to prevent many of the ambiguous name references of ``path_name`. These ambiguities arise from region labels that are optional and anomalies in the LRM concerning ``path_name`. For example, unlabelled equivalent process and overloaded subprogram calls are disambiguated in `vhpiFullNameP`.

`vhpiFullNameP` is defined for explicit and implicit declarations.

`vhpi_handle_by_name()` can be used with names denoting declarations, `indexedNames`, `selectedNames`, `attrNames` denoting user defined attribute names, or signal valued attributes which denote signals (predefined attributes which `vhpiAttrKindP` property return `vhpiSignalK`).

For slice names, `vhpi_handle_by_name` is only able to find handles for slices that are visible in the original VHDL source. Indices if specified in the name, must only involve literals.

`vhpi_handle_by_name` of a `vhpiFullname` to a subprogram identifier name returns the subprogram declaration (`vhpiFuncDeclK` or `vhpiProcDeclK`) except if there is a dynamically elaborated subprogram call of the same name in the same region, in that case the `subpCall` shadows the `subpDecl`.

Additionally if the handle to look up denotes an enumeration literal that is overloaded, the

`vhpiSignatureNameP` property must be appended to the `vhpiFullNameP` of the enumeration literal in order to return unambiguously a handle.

6.2.1.1 Find by Absolute Path Name

The `vhpi_handle_by_name` function uses a case insensitive comparison of the search string to the `vhpiFullNameP` value, except where a component of the name uses extended identifiers. That component of the name will be compared with case sensitivity.

An absolute path name is indicated by a search string which begins with `':'` or `'@'` (`@` for elaborated package references). The name provided must exactly match the `vhpiFullNameP` of an object, whose handle will be returned.

The scope reference handle must be consistent with the search string, i.e., either be a NULL handle, the handle of a region along the path to the desired object, or an elaborated package instance in which the object can be found.

1 The scope reference handle functions to narrow the domain of the search. For a region handle, the search
2 is restricted to the region, any of its internal region, or their sub regions. For an elaborated package, the
3 search is restricted to the package's elaborated declarations.

4 **6.2.1.2 Find by Relative Path Name**

5 This is indicated by a search string which does not begin with a ':' or '@' character. The search string will
6 produce the same result as if the vhpiFullNameP of the scope reference handle was prepended to the search
7 string, formulating an absolute search. The scope reference handle shall not be null.

8 The scope reference handle effectively establishes the top most region or an elaborated package context
9 from which to search. There is no manner in which a relative name search will find an object above this
10 region or package. In particular, this is not a search that mimics VHDL name resolution, in which some
11 declarations outside an immediate region might be visible.

12 **6.2.2 Uninstantiated Model Access (Library unit access)**

13 Having access to the uninstantiated model in VHPI is a separate capability identified as the
14 "vhpiProvidesPostAnalysis" capability (see 1.1.2). The UML description and name properties provide the
15 framework for vhpi_handle_by_name working uniformly across both information models.

16 In the uninstantiated context, the vhpiFullNameP returns a string identical to the same string returned by
17 the vhpiDefNameP property.

18 Additionally if the handle to look up denotes an enumeration literal or a subprogram call that is
19 overloaded, the vhpiSignatureNameP property must be appended to the vhpiFullNameP of the enumeration
20 literal or subpCall in order to return unambiguously a handle otherwise the specification of the returned
21 handle by vhpi_handle_by_name is not specified by the standard.

Deleted: .

22
23
24 The string value of the vhpiDefNameP property passed to vhpi_handle_by_name returns a handle to a
25 post-analysis object.
26

27 **6.2.2.1 Find by Absolute Path Name**

28 This is indicated by a search string which begins with '@'. The name provided must match the
29 vhpiDefNameP of an object whose handle will be returned.

30 The vhpi_handle_by_name function uses a case insensitive comparison of the search string to the
31 vhpiDefNameP value, except where a component of the name uses extended identifiers; that component of
32 the name will be compared with case sensitivity.

33 The scope reference handle must be consistent with the search string, i.e., either be NULL, the handle of
34 the logical library along the path to the desired object, or the design unit containing the desired object.

35 The scope reference handle functions to narrow the domain of the search. For library access, it allows the
36 search to be restricted to a specific logical library or design unit.

37 A null scope reference handle indicates that the search is done over all the logical libraries known to the
38 tool.
39

40 **6.2.2.2 Find by Relative Path Name**

41 This is indicated by a search string that is recognizable as a relative path, meaning it does not begin with a
42 '@'. The search scope reference handle shall not be null. The search string will produce the same result as
43 if the vhpiDefNameP of the scope reference handle was prepended to the search string, formulating an
44 absolute search.

7. Foreign models interface

This chapter describes how to interface VHPI/ANSI-C foreign models or applications with a VHDL tool. It describes the specification, invocation and execution of foreign VHPI models and applications. This chapter is organized as follows:

- section 7.1: overall flow of execution of a mixed VHDL/VHPI foreign design,
- section 7.2: VHDL specification of foreign models,
- section 7.3: registration of VHPI foreign models and applications,
- section 7.4 : elaboration of VHPI foreign models,
- section 7.5: execution of VHPI foreign models and applications,
- section 7.6: VHDL context passing
- section 7.7: save, restart and reset of foreign models.

7.1 The phases of execution of a VHDL/VHPI mixed design

As defined by VHDL, there are two kinds of foreign models, architectures and subprograms which can themselves be either functions or procedures. VHPI foreign models have a VHDL declaration and a VHPI/ANSI-C behavior implementation. The VHDL declaration denotes the interface of the foreign model and other local declarations: for a foreign entity/architecture, it includes the entity and architecture declarative parts, and for a foreign subprogram, it includes the subprogram declaration (if present), or subprogram specification (if no declaration). Note that a foreign subprogram does not need to have a subprogram body. VHPI also provides the capability of invoking a foreign VHPI application at a given point during a VHDL session such as analysis, elaboration or simulation. That application is an autonomous VHPI program that can run concurrently with the simulation or can be called at a defined point in time during a VHDL session. Typical third-party tool applications such as signal monitoring, VHDL code profilers, hierarchy browsers can be developed and integrated as VHPI foreign applications.

We distinguish several phases in the life of foreign models and applications:

1. Registration
2. Elaboration
3. Initialization
4. Simulation run-time execution
5. Termination
6. Save/restart or reset.

The following paragraphs describe the different phases in details. All phases except for the registration and save/restart/reset phases, refer to already known phases in a VHDL tool.

Registration:

Registration is the first stage of execution of a VHDL/VHPI session. VHDL tools must support a registration mechanism for the VHPI foreign models and applications. The registration phase must occur before the `vhpiCbStartOfTool` callback which is the first defined time point for callback registration. Typically a developer of foreign models and applications would have to provide a C dynamic or static library which contains the compiled code of the VHPI based models and applications and at least a function to register the foreign models and applications into a VHDL session. After registration, the foreign model and application behaviors are defined, that is, a given VHPI based implementation has been associated with a foreign model or application. The required associations are defined in section 7.3. The registration of a model or application records the association(s) between C behavior and a VHDL model and does not necessarily do the symbol binding. The symbol binding may occur between the registration phase and the phase when the symbol functions need to be used. For VHPI applications the symbols need to be resolved before the `vhpiCbStartOfTool` callbacks.

NOTES:

- 1 - The registration function or also called bootstrap function is the only required globally visible entry point for registering a library of VHPI C models or a foreign application.

2 - There is no predefined name for the bootstrap function. The name of the bootstrap function must be supplied to the VHDL tool using an implementation defined mechanism.

3 - There is no predefined name for the foreign libraries. As a consequence, several libraries can be registered in the same VHDL session.

4 - The tool has the flexibility to determine when the binding of the model name to the C functions occurs (during registration or late during elaboration/simulation). The VHDL tool is free to register all the foreign models included in a library at once, or to register them one at a time when the foreign model is encountered during elaboration. However, the various C functions providing elaboration, initialization or simulation of a foreign model need to be known at the execution of the given phase.

5 - A library of foreign models or a foreign application may have several bootstrap functions.

6 - The binding can occur anytime from the point of registration until the point of use. The point of use of an application is immediately prior to the `vhpiCbStartOfTool` callback.

Elaboration:

Elaboration consists of the creation of the model instances that are involved in a VHDL design. Elaboration occurs after the model that is being elaborated has been registered and before simulation initialization. The declarative parts of VHPI foreign architectures are statically elaborated while the formal parameters of VHPI foreign subprograms are dynamically elaborated (there is no elaboration of the subprogram declarative part). The elaboration of the foreign models including the elaboration of the declarative and statement body parts is defined in section 7.4. It is an error if when elaborating of a foreign model, the C function for the elaboration of the foreign model is not known or not found. Initial values computed during the elaboration of an object declaration may involve the execution of a foreign function. Creation of a VHPI process and driver may be done during elaboration of a foreign architecture. The initial values of the ports of the foreign models or driving values of the VHPI drivers can be set with `vhpi_put_value` by the elaboration function of a foreign architecture.

Initialization:

Simulation initialization refers to the phase where signal driving and effective values are initially computed and processes are executed for the first time. The computation of a signal effective or driving value may involve the execution of a foreign function (resolution or conversion). The initialization function of each foreign architecture gets called during the initialization phase. The simulation function of a foreign subprogram may get called as a result of process execution. It is an error if the initialization function of a foreign architecture or simulation C function of a foreign subprogram is not found at the initialization phase if it needs to be executed.

Simulation runtime execution:

Simulation consists of the execution of the previously elaborated and initialized design. The execution of the foreign models or applications at appropriate times is accomplished through registration of callback functions for various reasons. These callbacks are either dynamically registered as the simulation proceeds or may have been registered during initialization. The control flow of a concurrent region defined by a foreign architecture can be emulated by callbacks.

Termination:

The termination phase is the last phase after which execution of other phases is not permitted. Termination consists of going back to a clean state before exiting the present VHDL session. The termination of a VHDL session can happen for several reasons (end of simulation, fatal error...). Termination is the last stage of execution of a VHDL session. Termination involves calling the registered `vhpiCbEndOfTool` callbacks. This callback reason gives the ability for foreign models and applications to take proper action to free any allocated resources, close files and terminate cleanly.

Save, Restart, Reset:

The mechanisms for saving, restoring or resetting foreign models are described in section 7.7. Foreign models and applications have the capability to save, restart or reset their state. These operations occur at a clean state of the simulation cycle: all scheduled events for that simulation cycle must be executed before the operation takes place.

Informative note: Foreign models should not assume that the memory they allocate or the files they open persist between any of these phases. In fact, any of these phases could belong to a different process.

7.2 Foreign models specification

The string of a foreign attribute that is decorating a VHPI foreign architecture or subprogram follows a VHPI standard syntax. There are two standard syntax: one which specifies an indirect binding of the foreign model behaviours and another one which specifies a direct binding of the foreign model behaviours.

7.2.1 Foreign attribute syntax

7.2.1.1 Standard indirect binding mechanism

Foreign VHPI architectures:

attribute FOREIGN of <architecture_name>: architecture is
 "VHPI <library_name> <model_name>"

Foreign VHPI procedures and functions:

attribute FOREIGN of <subprogram_name[signature]>: procedure | function is "VHPI <library_name>
<model_name>"

- 1) The "VHPI" identifier indicates that this foreign model has a VHPI based implementation and that the binding is a standard binding.
- 2) <library_name> is the logical name of the C library. The mapping to the physical library is implementation dependent.
- 3) <model_name> identifies a VHPI based model implementation for a foreign architecture or subprogram.
- 4) The foreign attribute string must be locally static and the string syntax must be as follows:
"VHPI {<space_character>} {graphic_character} {<space_character>} {graphic_character}"

The space character can either be the space or the non breaking space character.

<space_character> := SPACE | NBSP

The string should start by VHPI keyword and should consists of two sets of graphic characters separated by at least one space character.

VHDL LRM 1076-1993 modifications needed page 72 for foreign attribute specifications.

NOTES:

- The analysis of the foreign string does not yield any interpretation of the value of the foreign string.
- The elaboration of the foreign attribute specification may involve some checking depending on a vendor implementation (checking for the existence of the C library, and existence of the foreign model).
- The name of the C library containing the foreign models need not to be the same as the name of the VHDL logical library which contains the VHDL component declarations and entity shell declarations of the foreign model. In the example below, the VHDL library which contains the foreign model component declarations is the VHDL library "foreignmodels" while the C foreign models implementation live in a C shared library named foreignC.<platform dependent_suffix>.

Example:

```
-- VHDL source file containing the specifications of foreign components
-- and subprograms
-- the package containing the declarations
package packshell is
    component C_and
```

```

1      port(p1, p2: IN bit; p3: OUT: bit);
2      end component;
3  end package;
4
5  -- the foreign procedure and function declarations
6  procedure myproc(signal f1: OUT bit ; constant f2: IN integer);
7      attribute foreign of myproc: procedure is
8          "VHPI foreignC myCproc";
9  function myfunc(signal f1: IN bit) return integer;
10     attribute foreign of myfunc: function is
11         "VHPI foreignC myCfunc";
12
13 end package packshell;
14
15 -- VHDL source file containing the design units
16 -- the entity/architecture declarations of the foreign architecture.
17 entity C_and is
18     port (p1, p2: IN bit; p3: OUT: bit);
19 end C_and;
20
21
22 architecture My_C_gate of C_and is
23     -- foreign attribute
24     attribute foreign of my_C_gate :architecture is
25         "VHPI foreignC myCarch";
26 begin
27     end architecture My_c_gate;
28
29
30 library foreignmodels; -- the VHDL library which contains the VHDL shell

50         va = myfunc(s1);    -- foreign function call myfunc
51     end process;
52 end my_vhdl;
53

```

54 7.2.1.2 Standard Direct Binding mechanism

55 This binding mechanism accomplishes both the registration and binding of the foreign model.
56 A VHPI implementation may also provide direct binding to the C behavior by providing the C library and
57 function names for the foreign model in the foreign attribute string.

In the case of foreign architectures, the string shall contain four tokens, each separated by one or more SPACE characters. Escaped identifiers can be used as tokens to specify platform specific names.

The first token shall be the keyword VHPIDIRECT.

The next token shall either be the NULL token or the name of the C library where the C functions modeling the behaviour of the foreign model are defined.

The next token shall be the name of the C function modeling the elaboration of the foreign architecture or NULL if none is required.

The next token shall be the name of the C function representing the initialization of the foreign architecture or NULL if none is required.

The library name shall not have any suffix.

Note 1: The library name is useful to distinguish C functions of the same name living in different C libraries. If the library name is NULL, the search of the C functions is vendor specific.

In the case of foreign subprograms, the string shall contain three tokens, each separated by one or more SPACE characters.

The first token shall be the keyword VHPIDIRECT.

The next token shall either be the NULL token or the name of the C library where the C functions modeling the behaviour of the foreign model are defined.

The next token shall either be the NULL token or the name of the C function modeling the execution of the foreign subprogram. See Note 2.

Note 2: If the NULL token is given in place of the name of the execf function of the foreign, the name of the C function is assumed to be the name of the VHDL subprogram declaration in the case specified in the VHDL file.

Foreign VHPI architectures:

attribute FOREIGN of <architecture_name>: architecture is
“VHPIDIRECT <library_name> <elabf_name> <execf_name>”
where <library_name> <elabf_name> or <execf_name> can be the NULL tokens.

Foreign VHPI procedures and functions:

attribute FOREIGN of <subprogram_name[signature]>: procedure | function is
“VHPIDIRECT <library_name> <execf_name>”
where <library_name> and <execf_name> can be the NULL tokens.
The foreign attribute string must be locally static and must be a string that starts with the VHPIDIRECT keyword.

7.3 Registration

7.3.1 Delivery and packaging of libraries of foreign VHPI models or applications

The standard does not define how a foreign library name and its corresponding bootstrap function are exchanged between a VHDL tool and a library developer.

The standard requires that models and applications be delivered packaged into either C dynamic (shared) or static (archive) libraries.

Foreign models and applications can be registered through a tabular file. A tabular registry file shall be provided when using the VHPI indirect foreign attribute syntax,

7.3.1.1 Tabular registry format

The tabular registration consists of providing a textual registry file which contains the registration information of foreign models and applications in a standard defined format. Each line of the registry table defines the registration of exactly one model or application or library of models.
The format of each line of the registry file is the following:

For a foreign architecture:

```
<library_name> <model_name> vhpiArchF <elab_fctn_name> | null <initialization_fctn_name>
```

For a foreign subprogram:

```
<library_name> <model_name> vhpiFuncF | vhpiProcF null <execution_fctn_name> | null
```

For a foreign application:

```
<library_name> <application_name> vhpiAppF <bootstrap_fctn_name> null
```

For a library of foreign models:

```
<library_name> null vhpiLibF <bootstrap_fctn_name> null
```

Comments may be included in the file, each comment line must start by a "--" character. The library, model, application and function names must be formed with graphical characters and can be extended identifiers.

The elaboration, execution and bootstrap function names should be the C source function names. One or more spaces can occur between names. The null token should be entered in the place of a C function name if no function name is provided. In the case of a null execution_fctn_name for a foreign subprogram, the name of the function defaults to the name of the model name.

If several bootstrap functions are associated with a library, an entry for each bootstrap function must be in the registry file.

Example:

Registry file contents example

```
--<library_name> <model_name> <kind> <elab_fctn_name> <sim_fctn_name>
```

```
-- registration of a foreign architecture
```

```
myClib orgate vhpiArchF elab_gate init_gate
```

```
-- registration of a foreign function
```

```
myClib myfunc vhpiFuncF null sim_myfunc
```

```
-- registration of a foreign application
```

```
myCapp appl vhpiAppF boot_myapp null
```

```
-- registration of a library of models
```

```
myClib null vhpiLibF bootlib null
```

Example of a library of models function registration

```
void boot_lib
```

```
{
```

```
    for each model in the library
```

```
        vhpi_register_foreignf()
```

```
}
```

Note: The names, number of and locations of the registry files are not predefined by the standard.

7.3.2 Registration functions for foreign models and applications

7.3.2.1 Registration and binding of a foreign model

A bootstrap function which registers models of a library shall use the standard VHPI function

vhpi_register_foreignf(). This function is called during the registration phase for each foreign model and

provides information such as C function entry points for the various phases defined for this kind of foreign

model. Different pieces of information are needed for a foreign architecture, procedure or function. A data structure of type *vhpiForeignDataT* is filled with the necessary information by the caller (bootstrap function). A pointer to that data structure is passed as an argument to *vhpi_register_foreignf()*.

Note : The tabular registration of foreign architectures and subprograms should not use the function *vhpi_register_foreignf()*, as all the pieces of information required are expected to be in the tabular registration file.

Correct since it is a textual entry rather than a programmatical entry but the tool who is reading the tabular form may use *vhpi_register_foreignf()*

The registration of a foreign model corresponding to a foreign architecture should provide back to the VHDL tool the following pieces of information:

- the library name,
- the model name,
- the model kind,
- a function pointer to the elaboration function for the architecture statement part or null if there is no user-defined elaboration,
- a function pointer to the initialization execution function for the architecture statement part.

The registration of a foreign model corresponding to a foreign procedure or function should provide back to the VHDL tool the following pieces of information:

- the library name,
- the model name,
- the model kind,
- a function pointer to the simulation function for the procedure or function body statement part.

Procedural Interface References:

See “*vhpi_register_foreignf()*”.

See “*vhpiForeignDataT*”.

See “*vhpi_get_foreignf_info()*”.

7.3.2.2 Registration of foreign applications

Direct binding of foreign applications is unspecified by the standard.

The registration of a foreign application consists of executing the bootstrap function of the foreign application at the registration phase. A VHDL tool must execute the bootstrap function of each VHPI foreign application that is needed for a particular VHDL session. The standard only requires that the developer of the application provides the library and the name of its bootstrap/registration function. The function name should be a visible symbol of that library. It is left to the vendor and provider to determine how the library is bound (for example dynamic, static linking or dynamic loading from command line arguments).

Applications may be put in the tabular form which is the standard registration mechanism. If they are used they must be bootstrapped before the *vhpiCbStartOfTool* callback. An implementation can define the way a user may indicate if an application is used for that session. The bootstrap function may register callbacks as defined in chapter 8.

vhpi_register_foreignf() can also be used for registering an application.

The registration of a foreign application should provide back to the VHDL tool the following pieces of information:

- the library name,
- the application name,
- the model kind, (in that case *vhpiAppKind*)
- a function pointer to the main function of the application program.

Procedural Interface References:

See “*vhpi_register_cb()*”

See “vhpiCbDataT”.

7.3.3 Registration and binding errors

1. Library name and/or model name used by a foreign attribute is not found in the registry.
2. The library cannot be located.
3. The registered C functions cannot be bound. This applies to functions registered for applications, libraries or models.

7.3.4 Restrictions

During the registration phase, the only part of the VHPI information model that can be accessed is the tool class (including the tool class properties, methods and operations). Other operations allowed are calls to *vhpi_register_foreignf()*, *vhpi_get_foreignf_info()* and *vhpi_register_cb()*, *vhpi_get_cb_info()*; registration of callbacks is also restricted to reasons that do not require to provide handles to elaborated objects. Also permitted are VHPI function calls to print (*vhpi_printf()*), check VHPI error *vhpi_check_error()*, and emit an assertion *vhpi_assert()*.

7.4 Elaboration of foreign models

7.4.1 Elaboration of foreign architectures

The elaboration of foreign architectures involves the elaboration of the declarative part of the entity and architecture.

Note: 156 and 157 of the VHDL LRM 1076-1993 need to be changed. The VHDL tool shall call the optional elaboration function which was registered for the foreign architecture.

7.4.2 Elaboration function

The elaboration function of the architecture is called in place of the elaboration of the statement body part of the foreign architecture. The prototype of the *elabf* function shall be identical to the prototype of callback functions:

```
PLI_VOID elabf(const vhpiCbDataT * cbDataP );
```

The *elabf* function is called with a pointer to a callback data structure of type *vhpiCbDataT*, the *obj* field should be a handle to the architecture instance (*vhpiCompInstStmntK* or *vhpiRootInstK*). The reason code shown by the *cbDataP* argument (type *vhpiCbDataT **) of the *elabf* function shall be “*vhpiCbStartOfElaboration*”. From the instance handle, information pertaining to this architecture instance and its elaborated entity can be obtained: for example elaborated ports and generics of that instance. The region class diagram depicts the relationships that can be traversed; the access permitted is described below. The *elabf()* function can:

- Access the current elaborated component instance and all its elaborated declarative part.
- Access the value of any of the instance declared items (including the generic propagated value)
- Create foreign drivers (*vhpiDriverK*) and foreign processes (*vhpiProcessK*) for that instance.
- Set the initial driving value of output ports and internal signals with *vhpi_put_value()*.

7.4.3 Elaboration of foreign subprograms

The elaboration of foreign subprograms involves dynamic elaboration of the subprogram. The subprogram formal parameters are elaborated when the subprogram call statement is encountered. No special elaboration C function entry point is needed. The “*elabf*” function pointer of the registration for a foreign subprogram shall be NULL.

Note: LRM modifications needed pages 156, 157, 163.

A foreign function can be called during elaboration phase to initialize declared items. The *execf* function is used to provide the initial value of the declared object.
Note: LRM modification needed for elaboration of declared objects involving foreign functions.

7.5 Simulation run time execution

7.5.1 Simulation of foreign architectures

During non-postponed process execution phase of the simulation initialization, the *initialization* functions of the foreign architectures are executed. This is the ONLY time the initialization function is invoked automatically by the simulator.

7.5.2 Initialization function

Architectures execution will be started once automatically at the simulation initialization phase by the invocation of the “*execf*” function and must sustain themselves throughout the entire simulation session by registering other C callback functions for simulation event reasons. The initialization function is specified by the *execf()* function. The prototype of the *execf* function is identical to the prototype of callback functions.

```
PLI_VOID execf(const struct vhpiCbDataS * cbDataP );
```

The *obj* field of the *cbDataP* argument should be set to the handle of the architecture instance that is initialized (*vhpiCompInstStmK*, or *vhpiRootInstK*). The reason code of the “*execf*” function should be *vhpiCbStartOfInitialization*. Memory allocated by the foreign architecture can be stored in the *user_data* field of the *cbDataP* of future registered callback functions.

The initialization function has access to the entire design, and has access to any VHPI function. There is no restriction on what the initialization function can do except calling *vhpi_register_foreignf* (registering a foreign model).

Informative note: there is no further control-flow for this foreign architecture instance except for callbacks that are registered during the initialization by the *execf* function.

7.5.3 Simulation of foreign subprograms

When a foreign subprogram call is encountered during VHDL execution, the simulation execution function is called: the control flow of a foreign subprogram call is determined by the VHDL simulation semantics.

7.5.4 Execution function

The simulation function for a foreign subprogram is specified by the *execf* function. The prototype of the execution function is identical to the prototype of a callback function.

```
PLI_VOID execf(const vhpiCbDataT * data );
```

The *obj* field of the callback data structure of type *vhpiCbDataT* should be a handle to the subprogram call being executed (*vhpiFuncCallK* or *vhpiProcCallStmK*). The reason code for a foreign subprogram call should be: “*vhpiCbStartOfSubpCall*”. The *user_data* field has no defined value.

There is no restriction on what the execution function can do. Handles to dynamically elaborated objects are only valid for the duration of the subprogram call. The user should not expect these handles to be valid

after the subprogram call has returned, nor that these handles be the same ones the next time the same subprogram call is executed. Note that the call-data context may be different for each subprogram call. Some vendors may do static elaboration of concurrent subprogram class and therefore handles to objects living in subprograms may be valid across subprogram calls. A property *vhpiIsInvalidP* is provided to check the validity of a handle.

Foreign functions must return a value. (). In order to set the return value of a function, the function call handle is the handle that should be used to set a value through *vhpi_put_value*. If the function return type is composite other than an array of scalars, then the users should iterate over the call handle to get to the level of a scalar or an array of scalars in order to set the return value. In the case of the return type being an array of scalars a single call to *vhpi_put_value* can be used to set the return value. The case of a function returning an unconstrained array requires a different treatment as outlined in the following paragraphs.

If the function returns an unconstrained array of scalars, then a single call to *vhpi_put_value* will suffice, in order to set the values of all scalar subelements. Alternatively, the user can choose to set the number of elements that the interface should expect in the return value, and then iterate over these elements using the relation *vhpiIndexedNames* and set each of the scalars separately. The function call handle will be the reference handle for this iteration. In order to achieve this, the first call to *vhpi_put_value* should use the flag *vhpiSizeConstraint*, with the *numElems* field in the value structure containing the number of elements that the interface should expect.

If the function returns an unconstrained array of composites, then the users are required to call *vhpi_put_value* with the flag *vhpiSizeConstraint* and set *numElems* in the value structure to the number of elements that the function will return. Subsequently, users can iterate over the subelements of the array using the relationship *vhpiIndexedNames* on the function call handle and set the value of each subelement separately.

For all calls to *vhpi_put_value* that set function return values, the flag parameter can be either *vhpiDeposit*, *vhpiDepositPropagate*, *vhpiForce* or *vhpiForcePropagate*. The semantics of setting the return value of the function are all exactly the same irrespective of the flag used. The return value is available immediately after the function return within the context of the expression that has the function call. If the function call is on the right hand side of a signal assignment statement, then the return value will be used in scheduling a transaction on that signal upon function return. The flag *vhpiRelease* has no effect when used with a function call handle or on any of the subelements of a function call handle for composite return types. In that case, an error should be generated.

The VHPI interface will check that the number of elements passed using *vhpiSizeConstraint* with *vhpi_put_value* matches the number of subelements that are actually set by the user with subsequent calls to *vhpi_put_value*, the interface should issue a warning in case of a size mismatch. If the number of elements returned by a function does not match the number of elements expected from the function within the context of the call, a runtime size error will be issued by the tool.

Calls to *vhpi_put_value* with *vhpiSizeConstraint* replace the previous size constraint for the specified reference handle. For vector of scalars, setting an explicit constraint is not necessary as a call to *vhpi_put_value* which supplies a vector of scalars will define an implicit constraint from the number of elements in the vector. However if an explicit size constraint was previously set, it is an error if the implicit constraint is different from that explicit size constraint.

An example to illustrate the use model for functions returning unconstrained types.

```
function foo(p1 : in std_logic;  
            p2 : in std_logic)  
    return std_logic_vector is  
begin  
end;
```

```

1
2 attribute foreign of foo:function is "VHPIDIRECT:mylib:fooC";
3
4 signal bar : std_logic_vector := foo('0', '1');
5 signal foobar : std_logic_vector(3 downto 0);
6
7 P : process (clk, reset)
8 begin
9     if (reset = '0') then
10         foobar <= "0000";
11     elsif (clk'event and clk = '1') then
12         foobar <= foo('1', '0');
13     end if;
14 end process;
15
16 In the first call to function foo, where it is the initialization expression for a signal declaration, the return
17 value can be any number of scalars. The range and direction of the constrained anonymous subtype of
18 signal bar will be determined by the implementation, while the size will come from the foreign
19 implementation of foo. In the second call to function foo, where it is used on the right hand side of a signal
20 assignment statement, the size has to be four. The constraints (3 downto 0) is assumed by the
21 implementation. In order to set the return value in either of the two calls to foo, the VHPI foreign function
22 can either use a single call to vhpi_put_value or use a vhpi_put_value with vhpiSizeConstraint and then
23 iterate over the scalar subelements and set them one at a time.
24
25 function finit(pl : in std_logic)
26     return std_logic_vector is
27 begin
28 end;
29
30 attribute foreign of finit:function is "VHPIDIRECT:mylib:finitC";
31
32 function foo(pl : in std_logic)
33     return std_logic_vector is
34 begin
35 end;
36
37 attribute foreign of foo:function is "VHPIDIRECT:mylib:fooC";
38
39 signal bar : std_logic_vector := finit('1');
40 signal foobar : std_logic_vector(3 downto 0);
41
42 P : process (clk, reset)
43 begin
44     if (reset = '0') then
45         foobar <= "0000";
46     elsif (clk'event and clk = '1') then
47         foobar <= foo(foobar(0));
48     end if;
49 end process;
50
51 In the call to function finit, where it is the initialization expression for a signal declaration, the return value
52 can be any number of scalars. The range and direction of the constrained anonymous subtype of signal bar
53 will be determined by the implementation, while the size will come from the foreign implementation of
54 finit. In the call to function foo, where it is used on the right hand side of a signal assignment statement, the
55 size has to be four. The constraints (3 downto 0) is assumed by the implementation. In order to set the
56 return value, the VHPI foreign functions can either use a single call to vhpi_put_value or use a
57 vhpi_put_value with vhpiSizeConstraint and then iterate over the scalar subelements of the call handle and
58 set them one at a time.

```

```

1
2 void finitC(vhpiCbDataT* pCbData)
3 {
4     int i;
5     vhpiValueT value;
6     vhpiHandleT param;
7     vhpiHandleT callHandle;
8     vhpiHandleT subelement;
9
10    // get the call handle and the first and only parameter
11    callHandle = pCbData->obj;
12    param = vhpi_handle_by_index(vhpiParamDecls,
13                                callHandle, 0);
14
15    // get the value passed into this call
16    value.format = vhpiEnumVal;
17    vhpi_get_value(param, &value);
18    vhpi_release_handle(param);
19
20    // set the size constraint to be eight, to indicate we intend
21    // to return a vector of eight elements
22    value.numElems = 8;
23    vhpi_put_value(callHandle, &value,
24                  vhpiSizeConstraint);
25
26    // we don't have to set anything in the value structure at this
27    // point as we intend to use the value passed in as the value of
28    // each subelement of the vector going out
29
30    // iterate over the subelements of the call handle and set each
31    // of them
32    for (i = 0; i < 8; i++) {
33        subelement = vhpi_handle_by_index(vhpiParamDecls,
34                                          callHandle, i);
35        vhpi_put_value(subelement, &value, vhpiDeposit);
36    }
37 }
38
39 void fooC(vhpiCbDataT* pCbData)
40 {
41     int i;
42     vhpiHandleT param;
43     vhpiHandleT callHandle;
44     vhpiValueT value;
45     vhpiEnumT enumval;
46     vhpiEnumT vector[4];
47
48    // get call handle and the first parameter
49    callHandle = pCbData->obj;
50    param = vhpi_handle_by_index(vhpiParamDecls,
51                                callHandle, 0);
52
53    // get the value of the parameter
54    value.format = vhpiEnumVal;
55    vhpi_get_value(param, &value);
56    vhpi_release_handle(param);
57
58    // we intend to return a four element vector where each scalar
59    // subelement is the flipped version of what was passed in
60

```

```

1   for (i = 0; i < 4; i++)
2       vector[i] = (isStdLogicZero(value.value.enumval))? vhpil : vhpil0;
3
4   // set the return value in one shot
5   value.format = vhpEnumVecVal;
6   value.value.enums = vector;
7   value.numElems = 4;
8   vhpil_put_value(callHandle, &value, vhpilDeposit);
9 }
10

```

11 7.5.5 Restrictions and errors

12 Any VHPI function except *vhpil_register_foreignf* can be called by foreign subprograms and functions.
13 Scheduling a zero delay transaction with *vhpil_schedule_transaction* or *vhpil_put_value* should generate a
14 runtime error if called during postponed process phase.

15 **Informative notes:** Foreign function can reach and update out-of-scope objects. The behaviour of foreign
16 functions declared as pure is not checked or enforced by the VHDL tool.

19 Procedural Interface References:

20 See “vhpil_register_foreignf()” for registering foreign models.
21 See “vhpilForeignDataT” for passing foreign model information.
22 See “vhpil_put_value()” for setting the returned value of a foreign function call.
23

24 7.6 Context passing mechanism

25 This section describes the mechanism by which interface and parameters are passed between the VHDL
26 and foreign-C functions, and for the case of foreign functions, how return values are passed back to the
27 VHDL tool.

28
29 The foreign C-function prototypes bear no relationship to the number or types of parameters used in the
30 VHDL declaration, parameters are accessed indirectly through the VHPI traversal methods if used when
31 the call to the C run-time function is executed.

32 A handle to the architecture instance or subprogram call is passed as the *obj* field of the callback data
33 structure which is the single argument of each *elabf* or *execf* function.

34 VHPI access functions can be used on that handle.

35
36 Some VHPI methods which can return foreign instances, subprogram calls or callbacks can be used to
37 transfer context between VHDL and C:

38
39 *vhpilCurRegion* shall return the currently active executing region instance from which the foreign model
40 call derived. *vhpilCurRegion* can return a foreign architecture instance or the foreign function procedure
41 call being executed.

42 7.6.1 Architecture instance

43 The architecture instance handle is passed through the *obj* field of the *cbDataT* structure. During
44 elaboration, only access to the entity architecture elaborated items are allowed.

45 During initialization of the architecture behaviour, all VHPI access is allowed. During initialization, the
46 architecture installs its behaviour by registering future callbacks; memory allocated by the foreign
47 architecture instance can be stored in the *user_data* field of the callback data structure of the registered
48 callbacks.
49

7.6.2 Subprogram Calls

When the flow of execution of VHDL code encounters a foreign subprogram call, call instance (context) information must be passed to the C-function implementation of the subprogram in order to perform the desired behavior. Context information is passed in a pointer to a callback data structure of type *vhpiCbDataT*. Information is provided as a handle to the VHDL subprogram call from which all necessary context information such as formal parameters can be obtained. Available data access is described by the class diagram for subprogram calls (refer 4.8.2). Because the subprogram call is an instance of a foreign subprogram, some relationships such as iteration on the sequential statements, will return NULL. Informative note: As a good programming rule, the foreign function code should access the formal parameters of the VHDL declaration and not attempt to reach outside the VHDL subprogram scope.

For foreign subprograms that are functions, a return value must be passed back to the caller. The VHPI function *vhpi_put_value()* should be used to indicate the return value of the function call. It will be a run-time error if:

- the C function fails to return the value,
- the size indicated by *vhpi_put_value* with *vhpiSizeConstraint* flag does not match the size of the value set by the subsequent *vhpi_put_value* calls (case of a foreign function returning an unconstrained array type),
- the value is the wrong size for the context of the call.

VHDL formal parameters are accessed through handles by traversing the relationships depicted by the class diagram of subprogram call. The VHDL passing mechanism for IN, INOUT and OUT parameters applies also to foreign subprograms.

The VHDL language observes some special handling of parameters in respect to the parameters being of mode IN, OUT or INOUT, as well as of class "constant", "variable", "signal" or "file".

The VHDL LRM 1076-2001 defines the following mechanisms which are being amended by VHPI

1. Values of **input** parameters of class **variable** or **constant** are **copied** from the actual parameters to the formal parameters at the **beginning** of the execution of the procedure or function. *vhpi_get_value* applied to formal parameters of input or inout mode shall return the value of the actual parameter as set at the beginning of the execution of the subprogram.
2. Values of the **output** parameters of class **variable** are **copied** from the formal parameters to the actual parameters at the **end** of execution of the procedure. Values deposited on output or inout formal parameters by *vhpi_put_value* are copied to the actual parameters at the end of the execution of the subprogram call.

When a parameter is of class **signal**, a **reference** to the actual signal parameter is **passed** into the procedure. This implies that changes made to the actual OUTSIDE of the procedure call will be **reflected** in the formal, similarly, if the formal is modified, the actual will reflect that change. In particular, transactions scheduled on a driver of the formal signal parameter of mode OUT are equivalent to transactions scheduled on the actual signal and vice-versa. Transaction scheduling from the C foreign code is performed with the function *vhpi_schedule_transaction()* or with *vhpi_put_value* (*vhpiDepositPropagate* or *vhpiForcePropagate*) *vhpi_put_value* with the other flags (*vhpiDeposit*, *vhpiForce*) deposits or forces a value on the actual signal.

Parameters of class **file** are also passed by reference. The opening mode of the file may be specified explicitly by the file declaration or be the default mode. VHPI access to a file parameter declaration is defined by the information model. Any other operation on a file parameter declaration is undefined.

Handles representing dynamic elaborated objects belonging to the subprogram call are only valid during the subprogram call execution. The user should not assume that the objects referred by these handles exist after the subprogram call completes neither that the same handles will be returned by the interface for the same subprogram call later during simulation. These handles are only valid (methods properties and operation can be obtained while the subprogram is active).

vhpi_get_value() method can be applied to formal parameters of mode IN or INOUT; this accesses the value of the VHDL formal parameter.
vhpi_put_value() method can be applied to formal parameters of mode OUT or INOUT; it will update the value or schedule a zero delay transaction on the VHDL formal parameter depending on the flags and class of the parameter. *vhpi_schedule_transaction* can be applied to a formal signal parameter of mode OUT or INOUT.

Note: Page 20 and 21 of the LRM has to be updated with foreign subprograms.

See “*vhpi_handle_by_index()*” to access a given formal parameter handle in the ordered iteration formal list.

7.7 Save, Restart and Reset

If the simulator supports save, restart and reset of a VHDL design then this capability can be extended to enable the foreign models and applications to save their state, restore from a simulation checkpoint or reset to time zero. In order to support this functionality, VHPI has defined save, restart and reset callback reasons as well as VHPI functions to write to (*vhpi_put_data()*) and read from (*vhpi_get_data()*) a saved checkpoint location. A foreign model/application that is interested in saving its state must register a callback for save. VHPI provides two callback reasons for each save, restart or reset action. The *vhpiCbStartOfSave*, *vhpiCbStartOfRestart*, *vhpiCbStartOfReset* callback functions are called respectively at the beginning of a save, restart or reset operation, while the *vhpiCbEndOfSave*, *vhpiCbEndOfRestart*, *vhpiCbEndOfReset* are called respectively at the end of the save, restart or reset operations. This is provided as a convenience to the user so that actions that need to be serialized can be guaranteed to happen in the correct order.

Note: A model does not need to register for both startOf and endOf reasons.

Foreign applications can also use the save/restart callbacks to save and restore their data from the simulation save location (see 7.7.4).

7.7.1 Saving foreign models

The standard requires that a compliant VHPI implementation save at least the restart callbacks during a save operation. This is so that when a restart operation is initiated all the models and applications that saved data are given the opportunity to restore saved data through their restart callbacks.

The standard also allows implementations to save handles, callbacks and user data and restore all of these with referential integrity. A tool vendor may indicate his capabilities to save and restore this information through the *vhpiAutomaticRestoreP* property. This property is an integer valued set of flags which can be queried from the tool class. The property expected values are *vhpiRestoreAll*, *vhpiRestoreHandles*, *vhpiRestoreCallbacks*, and *vhpiRestoreUserData*. A return value of *vhpiRestoreUserData* for *vhpiAutomaticRestoreP* implies that the tool will automatically save all user data in memory at the point of save and restore all data back into memory with referential integrity at the point of restart. For each flag of this property that is not set the user is responsible for saving necessary data to be able to recreate the state of the simulation at restart.

VHPI provides a function to write data in a save location:

```
PLI_INT32 vhpi_put_data(PLI_INT32 id, PLI_VOID *dataLoc, PLI_INT32 numBytes)
```

numBytes: the number of bytes to write out, must be greater than zero.

dataLoc: the address of the data to be saved.

id: a unique identifier of the location of the saved data that is used to retrieve the data during a restart operation. A new id is obtained by calling `vhpi_get(vhpiIdP, NULL)`.

returns: the number of bytes saved.

The function will write “*numBytes*” of the data starting at “*dataLoc*” into a simulation save location. The argument *id* identifies the saved foreign data set. This id determines how the data is written in the file. Data from multiple calls with the same id MUST be stored by the simulator in a manner that allows the opposite routine `vhpi_get_data()` to pull out the data of the same id in the order it was put in; data with different ids can be retrieved in any order.

Note 1: This allows the restart operation to be independent of the order the foreign models were saved.

The function returns the number of bytes that were successfully saved.

Note 2: The caller is responsible for determining if the number of bytes written corresponds to the number of bytes requested to be written.

The behaviour of `vhpi_put_data()` is only defined when invoked from a callback function that was registered for reason `vhpiCbStartOfSave` or `vhpiCbEndOfSave`.

There are no restrictions on:

- * how many times the `vhpi_put_data()` function can be called for a given id,
- * how many ids, a foreign model can create,
- * the order the foreign models put data into the saved location using different ids.

It is an error if the id passed in is zero or is an unknown id for this simulation session. It is an error if `numBytes` is equal to zero.

See example in the procedural interface reference for `vhpi_put_data()`.

The property tag `vhpiIdP` is defined `vhpi_get(vhpiIdP, NULL)` will generate and return a unique id to the caller. The id is unique for the simulation session. The id returned is different from zero. The id corresponds to an area in a saved location. The id is then used by `vhpi_put_data` to indicate where to save or by `vhpi_get_data` to indicate from where to restore data. `vhpi_get(vhpiIdP, NULL)` can only be called during a save operation. `vhpi_put_data()` and `vhpi_get_data()` functions will check if the id passed in is a legal id for this simulation session.

The id for a given foreign model or application should be different for each save operation of the same simulation session allowing to save different simulation checkpoints.

[Can I use same id across different check points?](#)

7.7.2 Restarting foreign models

VHPI provides a function to read data from a saved location:

```
PLI_INT32 vhpi_get_data(PLI_INT32 id, PLI_VOID *dataLoc, PLI_INT32 numBytes)
```

`numBytes`: the number of bytes of data to retrieve, must be positive.

`dataLoc`: the address of the data in which to place the data read.

id: a unique identifier that is used to specify the location of the data to read from the saved file. Must be greater than zero.

returns: the number of bytes retrieved.

The function will read “*numBytes*” from a simulation save location and place it at the address pointed by `dataLoc`. The memory for `dataLoc` must have been properly allocated by the caller and must be sufficient to

hold the data read. The first call for a given “id” will retrieve the data starting at what was placed into the save location with the first call with the same id to `vhpi_put_data()`. The return value will be the number of bytes retrieved. Each subsequent call will start retrieving the data where the last call left off for the given id. The `vhpi_get_data()` function can ONLY be called from a callback function that was registered for reason `vhpiCbStartOfRestart` or `vhpiCbEndOfRestart`. Callbacks for both restart reasons must be registered by either the callback user functions of reasons `vhpiCbStartOfSave` or `vhpiCbEndOfSave`. A compliant VHPI implementation will hence support a user’s intent to pass any unique ID for a particular save operation to the associated restart callbacks, so that they can faithfully restore saved data using one or both the restart callback reasons. Any type of data (for example int, long, char) can be retrieved, but pointer links and structures may need to be manually rebuilt on a restart. It will be a warning for the foreign model to retrieve more data than what was placed into the simulation save location for a given id. If this happens, the `dataLoc` will be filled with the data that is left for a given id and the remaining bytes will be filled with ‘\0’. It is acceptable for a foreign model to retrieve with a given id less data than what was stored for that id. It is an error if the id passed in is zero or an unknown id. The `vhpi_get_data()` function MUST only be called from a callback routine that was registered for reason `vhpiCbStartOfRestart` or `vhpiCbEndOfRestart`.

See example in the procedural interface reference for `vhpi_get_data()`.

Clarify when the id is obtained and passed to the restart operation. Save/restart model with ids. Where is the restart registered? Save is repetitive.

The restart sequence consists of

1. The tool loads the saved model,
2. The tool executes the `vhpiCbStartOfRestart` callback functions,
The VHPI client application checks the restore capabilities of the tool by querying the `vhpiAutomaticRestoreP` property.. Handles, callbacks and/or user data may not be restored by the tool:
`automatic = vhpi_get(vhpiAutomaticRestoreP, toolH)`
The `vhpiAutomaticRestoreP` property returns an integer value which indicates what has been restored; the defined standard integer values are defined by the enumeration type `vhpiAutomaticRestoreT`.
Depending on what is not automatically restored by the tool, the client or application may need to re-register the foreign models callbacks during the restart operation (remap the function pointers to the C functions), re obtain handles or rebuild its user data using `vhpi_get_data()`.
3. The tool executes the `vhpiCbEndOfRestart` callback functions,
4. `T_c = T_s` (time of the save). The tool starts simulation from the point of save.

```
typedef enum {
    vhpiRestoreAll      = 7,
    vhpiRestoreUserData = 1,
    vhpiRestoreHandles  = 2,
    vhpiRestoreCallbacks = 4,
} vhpiAutomaticRestoreT ;
```

Deleted: `vhpiAutomaticRestoreT` ¶

7.7.3 Reset of foreign models state

On a reset operation, after the `vhpiCbStartOfReset` callbacks have been executed, a compliant VHPI implementation shall remove all callbacks with the exception of `vhpiCbEndOfReset` callbacks. The removed callbacks will include those that were registered prior to simulation initialization. The

Deleted: ¶

Formatted: Bullets and Numbering

1 *vhpiCbEndOfReset* callback of a client or application will have to register all callbacks required to exist
2 during and after simulation initialization.
3 The reset operation winds the simulation time back to zero and to the beginning of initialization,
4 corresponding to step 1.0.1 in the annotated simulation cycle. Whenever a reset operation is initiated, a
5 compliant VHPI implementation will first execute all callbacks registered for reason *vhpiCbStartOfReset*.
6 The *vhpiCbStartOfReset* can be thought as “prepare for reset, clean up data structures, release any handle
7 which will become invalid after reset”. After *vhpiCbStartOfReset* callbacks have executed, the current
8 simulation time will be rewound to zero, followed by the execution of all user registered
9 *vhpiCbEndOfReset* callbacks. The initialization phase corresponding to step 1.0.1 in the annotated
10 simulation cycle will then be initiated. No callbacks other than *vhpiCbEndOfReset* shall be remaining after
11 the simulation time has been reset to 0 due to a reset operation. This means that any callback registered by
12 the user before simulation initialization is not required by the standard to remain between or after
13 *vhpiCbStartOfReset* and *vhpiCbEndOfReset* callbacks are run. The callback reason *vhpiCbStartOfReset* is
14 provided to client applications as a point at which they can cleanup any memory that has been allocated or
15 any state dependent data in memory. The callback reason *vhpiCbEndOfReset* is provided to enable client
16 applications to re-register any callbacks that existed at the start of initialization, including any
17 *vhpiCbStartOfInitialization* callbacks before the simulator begins execution of the initialization phase. As
18 all foreign model initialization code is re-run as part of the simulation initialization phase, client code does
19 not need to do anything for reset, other than re registering any callbacks that were registered before
20 initialization or re-registering debug environmental callbacks.

21
22 Note 1 : All callbacks that were registered during the course of simulation, starting at initialization phase
23 1.0.1 will be removed during reset. After all *vhpiCbStartOfReset* callbacks are run, a compliant simulator
24 will remove all callbacks, active, disabled or mature and all scheduled transactions will be annulled.

25
26 All handles that pertain to static data are still valid after a reset. Handles to dynamically elaborated regions
27 become invalid at the reset.

28
29 The reset sequence consists of:

- 30 1. Execute the *vhpiCbStartOfReset* callbacks, time = T_c (current time)
31 The client code is responsible for freeing the handles it requested, in particular handles which will
32 become invalid after the reset operation is completed (callback handles, transaction handles...)
- 33 2. The simulator removes all scheduled transactions and all user registered callbacks with the required
34 exception of *vhpiCbEndOfReset* callbacks.
- 35 3. Reset the VHDL simulation state to the beginning of initialization, $T_c = 0$ ns, ready to commence
36 execution of initialization phase 1.0.1 in the annotated simulation cycle.
- 37 4. Execute all user registered *vhpiCbEndOfReset* callbacks, opportunity for a client application to
38 register callbacks.
- 39 5. Initialization phase starts at 1.0.1 in the annotated simulation cycle.

40 41 7.7.4 Save, restart and reset of VHPI applications

42 Applications can use the save/restart callbacks to save and restore their state. An application which uses the
43 VHPI save/restart mechanism must request ids. Application data will be saved in the simulation saved
44 location identified by the id. Applications can request several ids. The restart callback for the application
45 must communicate the id.

46 An application can register callbacks for *vhpiStartOfReset* and *vhpiEndOfReset* to reset its internal state
47 when the simulation gets reset to time 0 ns.

48 7.7.5 Getting the simulation save and restart location

49 A string property is defined to be able to get the name of the simulation saved location.
50 *vhpi_get_str(vhpiSaveRestartLocationP, NULL)* returns the physical name string of the saved or restart
51 location. The save or restart location is determined by the tool. This property returns null if the tool is not
52 in a save or restart phase.

7.7.6 Restrictions

`vhpi_put_data()` can only be called from a callback routine that was registered for reason `vhpiCbStartOfSave` or `vhpiCbEndOfSave`.

`vhpi_get_data()` and `vhpi_get(vhpiIdP, NULL)` can only be called from a callback routine that was registered for reason `vhpiCbStartOfRestart` or `vhpiCbEndOfRestart`.

The `user_data` field of a callback data structure of reason `vhpiCbStartOfRestart` or `vhpiCbEndOfRestart` cannot be a pointer into memory because the simulation executable can restart at a different process address. The size of the `user_data` field for a restart callback is assumed to be an unsigned long.

The property `vhpiSaveRestartLocationP` returns a non null string when called during a save or restart operation.

Procedural Interface References:

See `vhpi_put_data()` to save data into a save location.

See `vhpi_get_data()` to retrieve data from a save location.

See “`vhpi_register_cb()`” to register save/restart and reset callbacks.

See “`vhpi_get_str()`” to access a string property.

8. Callbacks

Callback is the mechanism used for communication between the VHPI/C code and the VHDL tool. Typically the VHPI user code would register callbacks to happen for specific conditions. The VHPI interface defines a set of reasons for the callback conditions. This chapter begins with an overview of the callback mechanism. The VHPI functions that apply specifically to callbacks are discussed. Where callbacks appear in the information model and what information can be obtained is explained. The semantics of each callback is then defined. Finally, the execution of a callback is discussed, including what information is passed to it, and referential integrity considerations.

8.1 Callback Overview

A VHPI client application initially gains control at registration when its bootstrap function is called. Similarly, a foreign model gains initial control when its elaboration and/or initialization function defined at registration is called. Thereafter, VHPI allows an application or model to gain control at virtually all semantically significant points during the execution of the tool. The client first registers a callback of the desired kind, providing the function to be called and its relevant data. At the appropriate point, the callback is said to be triggered and VHPI calls its callback function. Some types of callbacks may only be called once, others repetitively. Callbacks are objects in the information model. A handle may be returned at registration or obtained later by navigation. VHPI provides the ability to manage callbacks, including disabling, enabling, or removing them.

8.2 Callback VHPI functions

Callbacks are objects in the VHPI information model. VHPI provides a few specific functions to create, obtain information, and manage them.

8.2.1 Registering callbacks

```
vhpiHandleT vhpi_register_cb(vhpiCbDataT *cbdatap, PLI_UINT32 flags);
```

The registration of callbacks can happen during analysis, elaboration, initialization or simulation run-time execution. The caller can request to have a callback handle returned by the registration function by setting the flag argument to *vhpiReturnCb*. The information model for a callback is discussed in the next section. A callback has state: it is either enabled, disabled, or matured. The callback handle that is returned can be checked to determine the callback state. An integer property *vhpiStateP* can be used to get the callback state: a state could be either *vhpiMature* if the callback has occurred, *vhpiDisable* if the callback was disabled, or *vhpiEnable* if the callback is still active. The callback registration is immediate upon the call to *vhpi_register_cb()*. The callback is enabled by default but may be disabled at the installation registration if the callback registration flag (second argument) is set to *vhpiDisableCb*. The flag argument can be set to both *vhpiDisableCb* and *vhpiReturnCb*.

Ex:

```
cbHdl = vhpi_register_cb(&cbdata, vhpiDisableCb | vhpiReturnCb);
```

The information to set up the callback is passed by the user through a data structure of type *vhpiCbDataT* which must be allocated by the user. All memory for that structure must be allocated by the user, including the *vhpiTimeT* and *vhpiValueT* structures if needed. The *cbDatap* contents are only used to convey information to the VHPI server on the type of callback to register. The *obj* field of *cbDatap* may be set to a handle; the client code is free to release that handle after the callback has been registered with no impact on the callback registration. For certain time related callback reasons, the time data structure is needed to pass the time of the callback to be created. For callback on value change, the value structure is needed to pass the format in which the value of the object needs to be returned. The user allocated callback data structure can be reused to register multiple callbacks.

The callback data information is passed by the caller and must provide at least the following information:

- the callback reason,
- the callback function C pointer.

All other fields may or may not be filled up depending upon the callback reason (see sections **Error! Reference source not found.**, 8.4.6, 8.4.8).

The callback registration is immediate upon the call to *vhpi_register_cb()*. The *cbDatap* contents are only used to convey information to the VHPI server on the type of callback to register. The user allocated callback data structure can be immediately reused to register other callbacks.

The following is the type definition of the 1st parameter passed to *vhpi_register_cb*:

```
typedef struct vhpiCbDataS
{
    int reason; /* callback reason */
    void (*cb_rtn)(const struct vhpiCbDataS *cbdatap); /* callback
                                                         routine */
    vhpiHandleT obj; /* trigger object */
    vhpiTimeT *time; /* callback time */
    vhpiValueT *value; /* trigger object value */
    void *user_data; /* pointer to user data to be
                    passed to the callback
                    function */
} vhpiCbDataT;
```

The specification of any callback is defined in this 1st parameter and must provide at least the following information:

- the callback reason,
- the callback function C pointer.

All other fields may or may not be filled up depending upon the callback reason and user preference. If the time and value fields are not null, they must indicate a valid format for the callback. The time value is always represented in the base unit of the type **TIME**. The *user_data* field provides a mechanism to associate any essential client information needed by the callback function when it is executed. It is never examined or dereferenced by VHPI itself. It may be ignored or cast as a pointer to memory or any other data value of equivalent size to a *void** data type to suit the client's purpose. Further details of the *CbDataS* usage are discussed in 8.4 Callback Semantics.

8.2.2 Disabling and enabling callbacks

```
(PLI_INT32) vhpi_disable_cb(vhpiHandleT cbHdl);
```

```
(PLI_INT32) vhpi_enable_cb(vhpiHandleT cbHdl);
```

Any callback can be disabled and enabled respectively with *vhpi_disable_cb()* and *vhpi_enable_cb()*. When a callback is disabled and its trigger condition becomes true, the callback function shall not be called. If it is a one time callback, its trigger condition can never become true again and its state is changed to *vhpiMature*. If it is a repetitive callback, it remains in the *vhpiDisable* state. Any callback in the *vhpiDisable* state may be enabled, but a callback in the *vhpiMature* state can never be enabled. Repetitive callbacks never mature. Note that re-enabling a repetitive callback does not change any of its specification, only whether it is called or not when its trigger condition becomes true. For example, a *vhpiCbRepAfterDelay* callback is called after a specific delay that starts when it is registered and repeats. Disabling and enabling such a callback has no effect on the time it will next be triggered. Both functions return 0 on success and 1 on failure. A status of 1 should be returned if the callback is:

1 - being disabled, but is already disabled (vhpiDisable)
 2 - being enabled, but is already enabled (vhpiEnable)
 3 - or has already matured (vhpiMature).
 4 The severity of this error condition is vhpiWarning, which may be obtained by calling vhpi_check_error().
 5 can be used to determine the severity of the error. In that case it should be a vhpiWarning.
 6 The following callback reasons are repetitive callbacks: vhpiCbValueChange, vhpiCbForce,
 7 vhpiCbRelease, vhpiCbStmt, vhpiCbResume, vhpiCbSuspend, vhpiCbStartOfSubpCall,
 8 vhpiCbEndOfSubpCall, vhpiCbTransaction, vhpiCbRepAfterDelay, vhpiCbRepNextTimeStep,
 9 vhpiCbRepStartOfCycle, vhpiCbRepStartOfProcesses, vhpiCbRepEndOfProcesses,
 10 vhpiCbRepStartOfPostponed, vhpiCbRepEndOfPostponed, vhpiCbRepEndOfTimeStep,
 11 vhpiCbQuiescence, vhpiCbPLIError, vhpiCbEnterInteractive, vhpiCbExitInteractive.

12
 13 Note all the vhpiRep* callbacks are registered in a repeated manner for the same simulation cycle point as
 14 their respective non repetitive callback reasons. vhpiCbRepAfterDelay callback causes the callback
 15 function to be triggered after every elapsed simulation time equal to the delay specified in the time field.
 16 If a vhpiCbRepAfterDelay callback is enabled after it was disabled, the callbacks will be re-enabled for the
 17 times it was initially registered. The effect of disabling such a callback results in temporarily inhibiting it
 18 from triggering, the effect of enabling this callback has the result to allow it to trigger again.

8.2.3 Getting callback information

23 (PLI_INT32) vhpi_get_cb_info (vhpiHandleT cbhdl, vhpiCbDataT *cbData_p);
 24 Given a callback handle *cbhdl*, the VHPI server will fill up a vhpiCbDataT structure that has been allocated
 25 by the user with the equivalent original information which was passed by the user in the *cbData* structure
 26 at the time of registration of that callback handle. All memory for the cbDatap structure must be allocated
 27 by the user. This function can be called at any time by a VHPI application which holds a valid callback
 28 handle. The validity of a handle has to do with referential integrity and not the state of the callback.
 29 Information is available for any callback, whether it is enabled, disabled, or mature. The function returns 0
 30 on success and 1 on failure.

8.2.4 Removing callbacks

34 (PLI_INT32) vhpi_remove_cb(vhpiHandleT cbHdl)
 35
 36 Given a callback handle, this function will remove the callback; the callback will not occur anymore. It will
 37 also free the callback handle, thus invalidating it. In contrast, just freeing the callback handle with
 38 vhpi_release_handle() frees the memory associated with the callback handle but does not remove the
 39 callback. In this later case, the callback will still be triggered according to its specification and an
 40 equivalent callback handle can still be re-obtained by the callback access methods (see section 8.3.1)
 41 depicted by the callback class diagram. The function returns 0 on success and 1 on failure.

8.3 Callback Information Model

44 The callback UML class diagram in Chapter 4 illustrates the methods and properties that are available for
 45 callbacks. A callback object is created when it is registered. A handle to it may be obtained at registration
 46 or at a later time using the methods described below. The handle so obtained remains valid until released
 47 by the user. The callback object itself exists until it is removed and there are no valid handles referencing
 48 it. One time callback objects are removed automatically under certain conditions.

8.3.1 Callback methods

Iteration on `vhpiCallbacks` from the tool (designated by a NULL reference handle) will return handles for all callbacks that are existing at the time of the query. It will return handles to callbacks that are either enabled or disabled, but mature callbacks are not returned. The only way to have a valid handle to a mature callback is to obtain the handle at registration or by iteration before the callback has matured. All callbacks are returned by the iteration to the caller even if the caller did not register these callbacks. VHPI has no concept of client identity that would allow otherwise. Given a callback handle, `vhpi_get_cb_info` can obtain the `cbDataS` of the original registration, then the caller can filter out callbacks of interest by looking at the function pointers or other information in the `cbDataS`. The preferred method of keeping track of callbacks is to retain handles obtained at registration.

Informative note: Looking at the function pointer address is the only way to recognize one's own callbacks, provided there is a way of comparing the address to the complete set of functions used to register callbacks and no other applications have registered callbacks with those functions. No assumptions can be made about the contents of the `user_data` field which may be null or not be a valid memory address.

A one to one method (`vhpiCurCallback`) from a null reference handle will return the currently executing callback handle or null. This will provide a new handle of kind `vhpiCallbackK` owned by the client. The state of that handle will be enabled or matured. It can be used to immediately remove and/or release the callback, disable it, or any other operation allowed on a valid callback handle. Note that if the goal is register a one time callback that removes itself after it matures, the preferred method is never to obtain a handle and let VHPI cleanup after callback execution.

Note: An elaboration, initialization or execution function is not a callback. *vhpiCurCallback* when called from within an elaboration, initialization or execution function should return NULL.

Iteration from an object declaration will return handles to callbacks of reason `vhpiCbValueChange`, `vhpiCbTransaction`, `vhpiCbForce`, `vhpiCbRelease` that were registered with the `obj` field of the `vhpiCbDataT` argument set to the object declaration handle.

Iteration from a statement handle (concurrent or sequential) will return all `vhpiCbStmt`, `vhpiCbResume` and `vhpiCbSuspend`, `vhpiCbStartOfSubpCall`, `vhpiCbEndOfSubpCall` reason callbacks registered for that statement.

Iteration from an `indexedName` or `selectedName` will return callbacks of reason `vhpiCbValueChange`, `vhpiCbTransaction`, `vhpiCbForce`, `vhpiCbRelease` that have been registered for the object name indicated by the handle in the `obj` field.

Iterating from a driver handle will return all registered callbacks for reason `vhpiCbTransaction` and `vhpiCbValueChange` for this driver.

8.3.2 Callback properties

There are two integer type callback properties that can be queried given a callback handle.

`vhpiReasonP`: gets the callback reason

`vhpiStateP`: returns the callback state either `vhpiDisable`, `vhpiMature`, or `vhpiEnable`.

A callback state is said to be "mature" if the callback has occurred at the time of the query. This means specifically that if the `vhpiStateP` of the currently executing callback is obtained and it is a one time callback, it will already be in the `vhpiMatured` state. Repetitive callbacks never mature.

The callback reason specifies when a callback is supposed to occur.

8.4 Callback Semantics

This section defines all the specific kinds of callbacks for VHPI. They are described in categories of tool phase, object, foreign model, stmt, time, simulation cycle, action, and save/restart/reset. These are regarded as providing a basics set of callbacks for a client to gain control at all significant points during the VHDL tool's execution. Each callback is identified by a callback reason, which is provided at registration along with any additional information required to fully specify the callback. The VHDL simulation cycle is referenced in some callback definitions and is annotated with specific VHPI callback reasons to support rigorous formal semantics. It is defined below before any discussion of individual callbacks.

8.4.1 The Annotated VHDL Simulation Cycle

There are references to the VHDL simulation cycle used to describe when some callbacks are triggered. The VHDL simulation algorithm is presented below with modifications that describe when the various VHPI callback reasons occur.

0. Initialization phase:

- 1)1.0.1) VHPI: cbStartOfInitialization callbacks are run including the implicitly registered foreign architectures callbacks (execf functions)
- 1.0.2) VHPI: cbStartOfNextCycle callbacks are run.
- 1.1.0) The driving value and the effective value of each explicitly declared signal are computed and the current value of the signal is set to the effective value. This value is assumed to have been the value of the signal for an infinite length of time prior to the start of simulation.
- 2)2.1.0) The value of each implicit signal of the form S'Stable(T) or S'Quiet(T) is set to True.
- 2.2.0) The value of each implicit signal of the form S'Delayed(T) is set to the initial value of its prefix, S.
- 3)3.1.0) The value of each implicit GUARD signal is set to the result of evaluating the corresponding guard expression.
- 4)4.0.1) VHPI: cbStartOfProcesses callbacks are run.
- 4.1.0) Each nonpostponed process in the model is executed until it suspends.
- 4.1.1) VHPI: cbEndOfProcesses callbacks are run.
- 5)5.0.1) VHPI: cbStartOfPostponed callbacks are run.
- 5.1.0) Each postponed process in the model is executed until it suspends.
- 6)6.1.0) The time of the next simulation cycle (which in this case is the first simulation cycle), T_n , is calculated according to the rules of step f of the simulation cycle, below.
- 6.1.1) VHPI: cbEndOfInitialization callbacks are run. A reset of the VHDL model would bring back the model to immediately after this point in the simulation cycle.
- 6.1.2) VHPI: cbStartOfSimulation callbacks are run.

1. Simulation cycle:

This marks the beginning of a time. The current time (T_c) has just advanced to the next time (T_n) where events or actions are scheduled to occur. Signal effective values have not changed yet.

1 a)
2 a.1.0) The current time, T_c is set equal to T_n .
3 a.1.1) VHPI: cbNextTimeStep callbacks are run except when simulation is complete according to the
4 rules of step a.2.0.
5 a.2.0) Simulation is complete when $T_n = \text{TIME'HIGH}$ and there are no active drivers or process
6 resumptions at T_n .
7 a.2.1) VHPI: cbStartOfNextCycle callbacks are run.
8 a.2.2) VHPI: cbAfterDelay callbacks are run.
9 b)
10 **Signal update, resolution and propagation**
11 The driving values of the signal drivers are computed by executing the transaction of their output
12 waveform relevant for that time. vhpiCbValueChange and vhpiCbTransaction callbacks on drivers happen
13 immediately when the driver has a value change or a transaction respectively. The basic signal effective
14 values are computed. Resolution functions are executed to compute resolved signal values. The driving
15 values of the basic signals are propagated through the port connections, conversion and resolution
16 functions. Non basic signal values are computed from the values of their sources. The effective signal
17 values are computed. The effective value of a signal becomes the new current value of that signal. A signal
18 is said to be active during the delta cycle if its new current value is different from the previous signal value.
19 If updating a signal causes the current value of that signal to change, then an event is generated for that
20 signal in that delta cycle. vhpiCbValueChange callbacks on signals occur during this phase b if that signal
21 had a value change.
22
23 b.1.0) Each active explicit signal in the model is updated. (Events may occur on signals as a result.)
24
25 c)
26 c.1.0) Each implicit signal in the model is updated. (Events may occur on signals as a result.)
27
28 d)
29 **Process execution**
30 The events determined at the signal update cause the resumption of processes sensitive to that signal during
31 this delta simulation cycle. These processes execute and may cause new transactions on the signal drivers.
32
33 d.0.1) VHPI: cbStartOfProcesses, vhpiCb(Rep)TimeOut, vhpiCbSensitivity callbacks are run.
34 d.1.0) VHPI: cbResume callbacks are executed for the non postponed processes which are going to
35 resume. cbResume callbacks occur before the process is executed.
36 For each non postponed process P, if P is currently sensitive to a signal S and if an event has
37 occurred on S in this simulation cycle, then P resumes.
38
39 d.1.1) VHPI: cbValueChange callbacks for variables occur immediately if the current process execution
40 causes the variables to change value
41
42 e)
43 e.1.0) Each non postponed process that has resumed in the current simulation cycle is executed until it
44 suspends. VHPI: cbSuspend callbacks are executed for the non postponed processes which were
45 suspended.
46 e.1.1) VHPI: cbEndofProcesses callbacks are run.
47
48 f)
49 f.1.0) The time of the next simulation cycle T_n is determined by
50 setting it to the earliest of:
51 1) TIME'HIGH
52 2) The next time at which a driver becomes active, or
53 3) The next time at which a process resumes.
54 f.1.1) VHPI: If $T_n \neq T_c$ cbLastKnownDeltaCycle callbacks are run and T_n is recalculated according
55 to the rules of step f.1.0.

f.2.0) If $T_n = T_c$, then the next simulation cycle (if any) will be a delta cycle.

g) **Postponed process execution**
The postponed processes are executed if this is the last delta simulation cycle for the time T_c . Postponed processes are executed until they suspend. The execution of postponed processes should not cause any new delta cycle.

g.1.0) If the next simulation cycle will be a delta cycle, the remainder of this step is skipped. {i.e. go to step a.2.0}

g.1.1) Otherwise, VHPI: `cbStartOfPostponed` callbacks are run.

g.2.0) Each postponed process that has resumed but has not been executed since its last resumption is executed until it suspends. VHPI: `cbResume` callbacks are executed for the postponed processes which are going to resume. `cbResume` callbacks occur before the process is executed. VHPI: `cbSuspend` callbacks are executed after the postponed process suspends.

g.2.1) VHPI: `cbValueChange` callbacks for a variable occur immediately if the current postponed process execution causes the variable to change value.

g.3.0) T_n is recalculated according to the rules of step f.

g.3.1) It is an error if the execution of any postponed process causes a delta cycle to occur immediately after the current simulation cycle.

h)

End of time step:
This phase follows the postponed process phase (if postponed processes exist) or the process execution phase. It marks the end of the current time T_c , the next time T_n is different from T_c .

h.1.0) VHPI: `cbEndOfTimeStep` callbacks are run.

h.1.1) If there are active drivers or process resumptions at T_n , then the remainder of this cycle is skipped, {i.e. go to step a.2.0},
Otherwise the simulation has reached a quiescent state that may be the end of simulation if then, go to i).

i)

Quiescence:
In this phase, simulation has reached a stable state.

i.1.0) VHPI: `cbQuiescence` callbacks are run. This allows potentially foreign models or applications to further stimulate the design.

i.1.2) T_n is recalculated according to the rules of step f.

i.1.3) It is an error if the execution of any `cbQuiescence` callback causes a delta cycle to occur immediately after the current simulation cycle.

i.1.1) If there are active drivers or process resumptions at T_n , then the remainder of this cycle is skipped, {i.e. go to step a.1.0}
Otherwise this is the end of simulation, go to j)

j)

End of simulation:
j.1.0) VHPI: `cbEndOfSimulation` callbacks are run.
j.1.1) Simulation terminates.

The callback reason defines when the callback will happen. In the following section, when describing a callback reason, we explain when the callback function triggers. For all callback registrations, the user must allocate a callback data structure of type `vhpiCbDataT` and set the fields relevant for that callback reason. For all callbacks, the *reason* and *cb_rtn* field (callback function pointer) must be set. If the time and value fields are not nul, they must indicate a valid format for the callback. The time value is always represented in the simulator precision. Additional settings are described for each callback reason.

There are three main categories of callbacks: event, time and action callbacks. The various callbacks are described below.

8.4.2 Object Callbacks

There are many kinds of objects in the VHPI information model, distinguished as having a runtime value. The object callbacks return control to the client when a dynamic aspect of the object changes.

All object callbacks are repetitive callbacks except for the optional foreign model timeout callback which has both a non repetitive and repetitive callback reason. They remain in effect until they are removed by calling *vhpi_remove_cb()*.

If at the registration of the callback, the *value* and *time* fields of the *vhpiCbDataS* structure are not null, they indicate that the value of the object and the time of the change are requested to be provided when the callback triggers. The *value* field is allocated by the user at the registration and is only used as an indication to obtain a value in a specified format when the callback triggers. Only the format field of the value structure must be set, there is no need to allocate a buffer for formats which require a buffer. The time field of the *cbDataS* structure must be set to a non NULL value at the registration; this non NULL value will not be dereferenced by the VHPI implementation. When the callback triggers, the entire *cbDataS* structure of the callback function is allocated by the interface, including the *time* and *value* structures. The *value* and *time* structures are filled up when the callback triggers with the *value* and *time* of the object which caused the callback routine to be invoked. The *cbDataS* structure of the callback function is read-only for the user.

8.4.2.1 vhpiCbValueChange

This callback reason tracks value changes of variables, signals (including the signal attributes delayed, stable, quiet and transaction if they are referenced in the design) and drivers. These could be either full objects, selected names, indexed names or drivers. The object kind can be *vhpiSigDeclK*, *vhpiVarDeclK*, *vhpiPortDeclK*, *vhpiSigParamDeclK*, *vhpiVarParamDeclK*, *vhpiIndexedNameK*, *vhpiSliceNameK*, *vhpiSelectedNameK*, *vhpiDriverK*, *vhpiParamAttrNameK*. For signals which are not OUT mode ports (*vhpiOutPortDeclK*), the callback tracks signal effective value change. For OUT mode ports, drivers and *vhpiOutPortDeclK* (out port of an inout port), the callback tracks the driving value. The callback on signal value change will fire if an event is generated for that signal. Callback functions for value change of signals and drivers and predefined signal attributes which define implicit signals such as 'delayed', 'stable', 'quiet' and 'transaction' may be executed during signal update and propagation up until but specifically before *cbStartOfProcesses* callbacks are executed. For signal class objects, only one callback will occur for the whole object even if more than one scalar element changes value in the same delta cycle. For variable class objects, the callback triggers as soon as the variable changes value, therefore many callbacks for the same variable object can be executed in the same delta cycle. Value change callbacks on variables, typically occur during the process or postponed process execution phase whenever a variable is updated during VHDL execution or with *vhpi_put_value*.

The registration of a value change callback consists in setting the *obj* field to the handle of the object subject to the callback on value change. The caller may request that the value of the object resulting from the value change and/or the time of the value change be returned in the callback data structure. If so, the caller needs to allocate a value and time structures for the fields of the *vhpiCbDataS* structure. The time and value structures specify the formats in which time and value of the object value change should be given when the callback function executes (for valid formats see *vhpi_get_value()*). Otherwise if the value and time of the value change callback are not requested, the value and time field pointers should be set to NULL. These value and time structure are only an indication for the registration of the callback. When the callback triggers, the callback, value and time structures are allocated by VHPI.

Notes: Callback on value changes cannot be placed for aliases of objects.

8.4.2.2 vhpiCbForce

This callback reason triggers if a variable, signal, or part of a variable or signal was forced to a value. The callback registration consists in setting the *obj* field to the handle of the object of interest. The caller can also request to get the value of the object after the force, if so, the value field must point to the address of a value structure that has been allocated by the caller. A valid format must be provided for the value. A forced value may happen because of a call to the VHPI function *vhpi_put_value(objHdl, &value, flags)*, where the flag value is set to *vhpiForce*, *vhpiForcePropagate* or from a force simulator command. If the *obj* field is null, then the callback should happen every time a force occurs on any object; when the callback triggers, the *obj* field will contain the handle of the object that was forced. The differences between the 2 types of forces are explained in section 9.3. For all objects, the callback triggers immediately when the object is forced.

Note: Signal valued attributes cannot be forced. Guard signals can be forced.

ISSUE: Should we list kinds? Note that drivers cannot be forced? If only a slice of the object was forced, return the entire object.

8.4.2.3 vhpiCbRelease

This callback reason triggers if a value release occurs to a variable or signal or sub-element thereof that was previously forced. The callback registration consists in setting the *obj* field to the handle of the object of interest. After the release has happened the value that was forced remains until it is overwritten by a new update. Consequently the value that the caller may request to get will still be the forced value. A value release may happen because of a call to the VHPI function *vhpi_put_value(objHdl, &value, flags)*, where the flag value is set to *vhpiRelease*, or from a simulator release command with the same semantics. If the *obj* field is null, then the callback should happen every time a release occurs on any forced object; when the callback triggers, the *obj* field will contain the handle of the object which force was released. A release can be applied during any of the phases and the callback function triggers immediately.

NOTE: A force or release accomplished either through *vhpi_put_value* with *vhpiForce* or *vhpiRelease* flags or through a simulator force or release command **does** not trigger value change callbacks.

8.4.3 Optional object callbacks

8.4.3.1 vhpiCbTransaction

A callback registered for that reason triggers when a driver transaction matures or when a transaction occurs on the signal. The driver value has been updated according to the transaction value. The *obj* field should be set to a driver or signal handle. The value and time of the transaction can be requested to be returned at the callback registration by providing pointers to user allocated value and time structures in the value and time fields. The callback triggers during signal update and propagation before value change callbacks for the signal.

8.4.4 Foreign models specific callbacks

8.4.4.1 vhpiCbTimeOut

A callback registered for this reason triggers during the process execution phase when the simulation time specified in the *time* field of the *cbData* structure has elapsed since the callback registration. The *reason*, *cb_rtn* and *time* fields are the only required fields which need to be set at the callback registration. This callback is equivalent to a process statement which would have two statements: the VHDL statements wait for time followed by the call to the callback function *cb_rtn*.

vhpiCbTimeOut is the non repeated version of the callback. **vhpiCbRepTimeOut** is the repeated version

vhpiCbTimeOut is a convenience that is equivalent to registering a *cbAfterDelay* timeout cbk which itself registers a *cbStartOfProcesses* callback. It is possible to emulate a postponed process which has a time out by registering a time out callback which itself registers a start of postponed callback.

8.4.4.2 vhpiCbSensitivity

A callback registered for this reason triggers during the process execution phase when an event occurred on any of the signals indicated by the *obj* field. The *obj* field must be set to a single signal handle or to a collection of signals. If the value field is not null, the *cbData* value.int field will indicate which signals in the collection had events. The set to 1 of a specific bit of the value.ints field will indicate the corresponding signals members in the collection in the *obj* field) which. The value.ints field is allocated by VHPI and is read only when the callback function executes.

If the *time* field is not null at the callback registration, when the callback triggers, the *cbData* time field should be set to the current absolute simulation time. It is possible to emulate a postponed process which has a sensitivity by registering a *vhpiCbSensitivity* callback which itself registers a *vhpiCbStartOfPostponed* callback.

It is a **repeated** callback.

Note: Due to the nature of postponed processes, the value you may obtain when the *startOfPostponed* callback execute may not be the value which triggered the callback.

8.4.5 Statement callbacks

The *vhpiCbStmt* and *vhpiCbResume* and *vhpiCbSuspend* *vhpiStartOfSubpCall* and *vhpiEndOfSubpCall* callbacks are repetitive callbacks. Other statement callbacks are one time only callbacks. The only fields in the *vhpiCbDataS* structure that shall need to be set up by the user are the *reason*, *obj*, *cb_rtn* and *user_data* (if desired) fields. When a statement callback occurs, the *cb_rtn* user routine is called and is passed a pointer to a *vhpiCbDataS* structure, the *reason*, *cb_rtn* and *user_data* fields shall be set to the *reason*, *cb_rtn* and *user_data* fields which were passed in at the callback registration and the *obj* field shall be set to the original statement or another statement as detailed in the description of each specific callback reason.

8.4.5.1 vhpiCbStmt

A callback registered for that reason triggers before a sequential statement executes. The callback registration consists in setting the *obj* field to the handle of a sequential statement or to the handle of a equivalent process statement. The parent scope of the sequential statement must be a static region (concurrent statement) or a dynamically executing or suspended region (procedure or function call). The statement handle must be an instantiated statement handle. In the case where the object handle is an equivalent process statement, the callback will trigger when it is about to execute the concurrent statement. When the callback triggers, the *obj* field is set to point to the sequential statement that is going to be executed in the case of a process or procedure call statement. For other equivalent process statements, the *obj* field remains the concurrent statement handle. No other fields except the *obj* and *reason* fields need to be set. In particular, the time and value fields are ignored. The callback function executes during the process or postponed process execution phases. The callback acts like a statement breakpoint. Note that an optimized VHDL implementation may have effect on the order in which callbacks occur and may prevent the registration of certain callbacks due to loss of the HDL source mapping. If a callback cannot be registered, an error should be generated. The table below describes the behavior of *cbStmt* for all possible statement kinds.

vhpiWaitStmt vhpiReportStmt vhpiAssertStmt vhpiVarAssignStmt vhpiSimpleSigAssignStmt vhpiNextStmt vhpiExitStmt vhpiReturnStmt	One callback occurs before the statement executes. For the wait and assert statements, the callback occurs before the condition expression is evaluated.
vhpiForLoop vhpiWhileLoop vhpiForeverLoop	For a <i>vhpiForLoop</i> statement, the callback should occur prior to a new value be assigned to the loop parameter. For a <i>vhpiWhileLoop</i> , the callback occurs prior to the evaluation of

	the condition expression on every iteration of the loop. For a <code>vhpiForeverLoop</code> , the callback occurs when the forever loop statement is first encountered, and on every subsequent iteration of the forever loop.
vhpiIfStmt vhpiCaseStmt	There are two cases: 1) if the <code>obj</code> field is set to a handle to the if or case statement (<code>vhpiIfStmtK</code> , <code>vhpiCaseStmtK</code>): the callback will trigger before the condition expression of the if stmt gets evaluated, or before the case expression of the case statement gets evaluated 2) if the <code>obj</code> field is set to a handle to a branch (<code>vhpiBranchK</code>) of the if stmt or case stmt: the callback will trigger before the condition of the branch gets evaluated for an if statement and before the first statement of the branch of the case statement gets executed.
vhpiNullStmt	This callback triggers just before the null stmt is executed.
vhpiProcCallStmt vhpiProcessStmt	The callback occurs just before the sequential statement inside the procedure call or process statement executes. When the callback triggers, the <code>obj</code> field points to the handle of the sequential statement that is going to be executed.

8.4.5.2 vhpiCbResume

A callback registered for that reason triggers before a process resumes execution. The callback registration consists in setting the `obj` field to a process or concurrent procedure call. When the callback triggers, the callback data argument of the callback function sets the `obj` field to the statement after the wait statement from where the process resumes or is set to the first statement in the process statement, if the process has a sensitivity list. The callback function executes during the process or postponed process execution phases.

8.4.5.3 vhpiCbSuspend:

A callback registered for that reason triggers just before a process or procedure suspends. When the callback triggers, the current region is the process about to be suspended. The callback registration consists in setting the `obj` field to a process or concurrent procedure call. When the callback triggers, the `obj` field of the callback data argument is set to a handle to the explicit wait statement if the process or procedure suspends on a wait, otherwise it is set to the last statement of process or procedure call it was originally set to. The current scope is still the process that is about to be suspended. The callback function executes during the process or postponed process execution phases.

8.4.5.4 vhpiCbStartOfSubpCall

A callback registered for that reason triggers when a subprogram call starts execution. The subprogram can either be a concurrent or sequential call of a VHDL or foreign subprogram. The callback registration consists in setting the `obj` field to a handle to the subprogram call. A handle to the subprogram call can be obtained by iterating on the sequential statements of a static region or dynamically executing region (subprogram call within a subprogram). A handle to a subprogram call cannot be obtained if the parent scope is not a static scope or an executing scope. When the callback function triggers, the subprogram formal parameters have been elaborated and their values assigned from the actual associations. No fields other than the `obj` and `reason` fields need to be set at the callback registration. The callback triggers whenever this specific instance of that subprogram call is invoked. This is a repetitive callback for a specific instance of that subprogram call.

8.4.5.5 vhpiCbEndOfSubpCall

A callback registered for that reason triggers when the subprogram call indicated by the `obj` field has completed execution. The subprogram can either be a concurrent or sequential call. The callback registration consists in setting the `obj` field to a handle to the subprogram call. The callback triggers when the subprogram call is about to return from execution. No fields other than the `obj` and `reason` fields need to be set at the callback registration. The intention is with this callback to be able to intercept and overwrite the returned value of the function call or the values of the out mode parameters of a procedure call before these values take effect in the calling code. This is a repetitive callback for a specific instance of that subprogram call.

8.4.6 Time callbacks

There are one time and repetitive time callbacks.

For all time related callbacks, the only fields in the *vhpiCbDataS* structure that shall need to be set up by the user are the *reason*, *time*, *cb_rtn* and *user_data* (if desired) fields. When a time callback occurs, the *cb_rtn* user routine is called and is passed a pointer to a *vhpiCbDataS* structure, the *reason*, *cb_rtn* and *user_data* fields shall be set to the *reason*, *cb_rtn* and *user_data* fields which were passed in at the callback registration and the *time* field shall be set to the absolute current time.

8.4.6.1 vhpiCbAfterDelay

A callback registered for that reason triggers at the absolute time computed by adding the current simulation time (at the registration *Tr*) plus the relative time delay (*d*) that is indicated by the time structure when the callback is registered. The callback triggers even if there is no transaction scheduled at this time; the callback function is executed at the beginning of the time step before values get updated and transactions processed. The *cbData* structure passed to the user callback function will include a time structure indicating the current simulation time. No fields other than the *reason*, *cb_rtn* and *time* fields need to be provided at registration. The *time* value of the *cbData* filled by *vhpi_get_cb_info* should be the relative time delay provided at the registration. All time values are given and interpreted in the simulator time precision.

8.4.6.2 vhpiCbRepAfterDelay

A callback registered for that reason causes the callback function to trigger at the current simulation time plus the relative time delay that is indicated by the time structure at the callback registration and at all subsequent intervals of that time delay value. If the current registration time is *Tr*, and a callback is registered for a delay of *d*, callbacks will be triggered at *Tr + d*, *Tr + 2d*, ... *Tr + md*. The callback triggers even if there is no transaction scheduled at this time; the callback function is executed at the beginning of the time step. If one disables the repetitive callback and re-enables it at time *Tn*, the callback will be reinstalled to trigger at times *Tr + d*, *Tr + 2d*, *Tr + md* where for all *m*, *Tr + md > Tn* and where *Tr* is the time the callback was registered, The callback is on the same schedule as defined when it was registered so that disable/enable has no effect on the schedule of the repetitive callback, except to temporarily inhibit it from triggering.

8.4.7 Simulation phase callbacks

For each type of callback, there is a single occurrence reason and a repetitive callback reason. If a phase callback is registered while or after that phase executes, the callback will not be triggered until the next time the tool executes that phase.

1 The only fields in the *vhpiCbDataS* structure that shall need to be set up by the user are the *reason*, *cb_rtn*
2 and *user_data* (if desired) fields. Any other field setting will be ignored. When a simulation phase callback
3 occurs, the *cb_rtn* user routine is called and is passed a pointer to a *vhpiCbDataS* structure, the *reason*,
4 *cb_rtn* and *user_data* fields shall be set to the reason, *cb_rtn* and *user_data* fields which were passed in at
5 the callback registration.
6

7 **8.4.7.1 vhpiCbNextTimeStep**

8 A callback registered for that reason triggers at the beginning of the next time slice that has driver
9 transactions and/or a *cbAfterDelay* or *cbRepAfterDelay* callback registered and where *Tn* (next time at
10 which the callback triggers) is different from *Tc* (current time at which the callback is registered). The
11 callback triggers at the beginning of a time step: the simulation time has just advanced, and no signal
12 values have been updated yet. Immediate signal value modifications done by *vhpi_put_value* with
13 *vhpiDepositPropagate* or *vhpiForcePropagate* flags, or by *vhpi_schedule_transaction* with 0 delay will take
14 place in the first delta cycle of the time step if they are invoked by this callback function.

15 **vhpiCbRepNextTimeStep** is the repeated version.
16

17 **8.4.7.2 vhpiCbStartOfNextCycle**

18 A callback registered for that reason triggers at the beginning of the next simulation delta cycle either for
19 the present time step or for the next time step if no more delta cycles are created for the current time step.
20 The callback function executes after *vhpiCbNextTimeStep*, before *vhpiCbAfterDelay* and before signal
21 update and propagation starts.

22 **vhpiCbRepStartOfNextCycle** is the repeated version.
23

24 **8.4.7.3 vhpiCbStartOfProcesses**

25 A callback registered for that reason triggers just before VHDL non postponed processes start execution.
26 Zero delay transactions scheduled by the callback function at this point take place in the next simulation
27 delta cycle.

28 **vhpiCbRepStartOfProcesses** is the repeated version.
29

30 **8.4.7.4 vhpiCbEndOfProcesses**

31 A callback registered for that reason triggers after all non postponed processes have executed for the
32 current delta cycle just before the next time *Tn* is computed. Zero delay transactions scheduled by the
33 callback function at this point take place in the next simulation delta cycle.

34 **vhpiCbRepEndOfProcesses** is the repeated version.
35

36 **8.4.7.5 vhpiCbLastKnownDeltaCycle**

37 A callback registered for that reason triggers just before the postponed processes execute (before
38 *vhpiCbStartOfPostponed* but after *vhpiCbEndOfProcesses* of the last delta. This callback triggers when
39 there is no more delta cycles to execute in this time step,. Zero delay transactions may be done by the
40 callback and can create a new delta cycle for this time step.

41 **vhpiCbRepLastDeltaCycle** is the repeated version.
42

43 **8.4.7.6 vhpiCbStartOfPostponed**

44 A callback registered for that reason triggers before the postponed processes execute and after
45 *vhpiCbLastKnownDeltaCycle*. No zero delay transactions may be done by the callback function because
46 this marks the end of all 0 delay delta cycles for this time step. An attempt to place zero delay transactions

with *vhpi_schedule_transaction()* or with *vhpi_put_value* with modes of *vhpiDepositPropagate* or *vhpiForcePropagate* should result in a runtime error.
vhpiCbRepStartOfPostponed is the repeated version. These callbacks occur even if there are no postponed processes.

8.4.7.7 **vhpiCbEndOfTimeStep**

A callback registered for that reason triggers at the end of the time step, the current time *T_c* has not advanced yet to the next computed time *T_n*. No transaction may be done by the callback function because this marks the end of a time step. . An attempt to place any transactions with *vhpi_schedule_transaction()* or with *vhpi_put_value* with modes of *vhpiDepositPropagate* or *vhpiForcePropagate* should result in a runtime error.

vhpiCbRepEndOfTimeStep is the repeated version.

8.4.8 Action callbacks

The only fields in the *vhpiCbDataS* structure that shall need to be set up by the user are the *reason*, *cb_rtn* and *user_data* (if desired) fields. When an action callback occurs, the *cb_rtn* user routine is called and is passed a pointer to a *vhpiCbDataS* structure, the *reason*, *cb_rtn* and *user_data* fields shall be set to the *reason*, *cb_rtn* and *user_data* fields which were passed in at the callback registration. If an action callback is registered at a given point during the tool session and that point precludes that action to ever take place, the tool is not required to detect such a situation.

All callback reasons except *vhpiCbQuiescence* and *vhpiCbPLIError*, *vhpiEnterInteractive*, *vhpiExitInteractive*, *vhpiSigInterrupt* are one time callbacks.

8.4.8.1 **vhpiCbStartOfTool**

A callback registered for that reason triggers when the tool starts its session, right after tool and VHPI interface initialization. The registration phase for VHPI has completed and all bootstrap functions have executed at this point. The tool class is accessible . Existing libraries and already analyzed models in those libraries are available in the uninstantiated information model. A session informally refers to the entire time a tool is executing. The only time any part of the VHPI information can be accessed is during a tool session. A session is delimited by the **vhpiCbStartOfTool** and **vhpiCbEndOfTool** callbacks.

8.4.8.2 **vhpiCbEndOfTool**

A callback registered for that reason triggers at the end of a tool session just before it exits. No access to any part of the VHPI information model is possible in the callback function, but final cleanup of a client application is possible including use of *vhpi_printf()*. All handles are invalid at this point and cannot be referenced, even to be released.

8.4.8.3 **vhpiCbStartOfAnalysis**

A callback registered for that reason triggers before analysis starts. The tool class is accessible. Existing libraries and their previously analyzed models are available.

8.4.8.4 **vhpiCbEndOfAnalysis**

A callback registered for that reason triggers at the end of the analysis phase. Access to post-analysis information models of previously analyzed design units analyzed before or during this session is possible.

8.4.8.5 vhpiCbStartOfElaboration

A callback registered for that reason triggers before the start of elaboration of a VHDL design. The access is the same as the one which is allowed for the cbEndOfAnalysis callback. In addition, this callback point allows the registration of callbacks which may be triggered during elaboration such as cbStartOfSubpCall of cbEndOfSubpCall.

ISSUE: I don't agree with this at all. This is virtually no different than vhpiEndOfAnalysis, except it does allow callbacks to be registered that may be triggered during elaboration for functions called in initializer expressions.

Note: Elaboration function for foreign architectures also have the reason field of the cbData structure set to vhpiCbStartOfElaboration; the access allowed in this circumstance is as defined in the foreign model chapter.

8.4.8.6 vhpiCbEndOfElaboration

A callback registered for that reason triggers at the end of the elaboration of a design. This provides a hook for elaborator back end applications Access to the post-analysis and post-elaboration information models is possible. Access to initial objects values determined by the elaboration of the object is possible and is the initial value assigned to the object as defined by the VHDL LRM section 12.3.1.4. Generic and port values at the end of elaboration are the ones determined by VHDL LRM 12

8.4.8.7 vhpiCbStartOfInitialization

A callback registered for that reason executes at the beginning of initialization. Access to post-analysis, post-elaboration and runtime information models is possible. Getting values has the same behaviour as getting values at cbEndOfElaboration. Updating values and scheduling transactions has unspecified behaviour.

8.4.8.8 vhpiCbEndOfInitialization

A callback registered for that reason executes at the end of initialization. Full Access to post-analysis, post-elaboration and runtime information models is possible. In particular getting values, updating values and scheduling transactions on drivers and signals is possible.

8.4.8.9 vhpiCbStartOfSimulation

A callback registered for that reason triggers when simulation starts, after simulation initialization. No other field settings are necessary for this type of callback. This callback occurs before any time or delta cycle callbacks. Access to post-analysis, post-elaboration and runtime information models is possible. Getting values, updating values and scheduling transactions is possible.

8.4.8.10 vhpiCbQuiescense

A callback registered for that reason triggers when a simulation reaches a quiet state and no transactions remain to be processed. The callback function can then schedule new non zero transactions with *vhpi_schedule_transaction()* and keep the simulation going. No other field settings are necessary for this type of callback. vhpiCbQuiescense shall occur before a vhpiCbEndOfSimulation callback. Access to post-analysis, post-elaboration and runtime information models is possible.

8.4.8.11 vhpiCbEndOfSimulation

A callback registered for that reason triggers when a simulation is complete normally according to the LRM. *vhpi_control* (*vhpiFinish*) will not cause a *vhpiCbEndOfSimulation* callback. If registered, a *vhpiCbEndOfTool* may follow a *vhpiCbEndOfSimulation* callback. Access to post-analysis, post-elaboration and runtime information models is possible. Getting values is possible.

8.4.9 Optional action callbacks

8.4.9.1 vhpiCbPLIError

Remove that callback, useless. A callback registered for that reason triggers when a VHPI error occurred. The callback function can then check the error. No other field settings are necessary for this type of callback. The error may or may not be caused by the application which registered the callback.

8.4.9.2 vhpiEnterInteractive

A callback registered for that reason triggers when the VHDL tool stops and enter the interactive mode. No other field settings are necessary.

8.4.9.3 vhpiExitInteractive

A callback registered for that reason triggers when the control is returned to the VHDL tool. No other field settings are necessary.

8.4.9.4 vhpiCbSigInterrupt

A callback registered for that reason may be triggered for an implementation defined abnormal event notification. No other field settings are necessary.

8.5 Save/Restart/Reset Callbacks

The reset and save callback are repetitive , restart callbacks are not.
No callbacks occur between a start of save and end of save or between a start of reset and an end of reset.
If the user interrupts the process during a save, then the data saved is not guaranteed to correspond to a valid restart point.
ISSUE: Should we allow other callbacks to happen in between these pairs of callbacks? Can you receive an interrupt callback? An error callback? Are both calls guaranteed to occur, unless the session is terminated?

vhpiCbStartOfSave, vhpiCbEndOfSave

A callback registered for reasons vhpiCbStartOfSave or vhpiCbEndOfSave triggers when a save command is processed by the tool. The vhpiCbStartOfSave callback occurs at the beginning of the saving of the VHPI models while the vhpiCbEndOfSave callback occurs at the end of the save operation. A model may not need to register for both callback reasons, but these two reasons are provided as a convenience to the user. For example, the user can use the vhpiCbEndOfSave reason to prepare for continuing simulation: as a consequence of saving data structures, the user may have to turn pointers of data structure into relocatable addresses, then after saving them and before continuing simulation, these must be fixed in memory to actual addresses. The fix up phase can be performed by the callback function registered for reason vhpiCbEndOfSave. When vhpiCbEndOfSave is called, the client is assured that all model instances that registered vhpiCbStartOfSave have been initially processed. Please refer to save and restart of foreign models Chapter 7. These callbacks can be registered at any time during simulation but the save operation and the save callbacks occur at a clean simulation state between simulation cycles (all scheduled events and processes for a delta cycle have executed and all steps for the next delta simulation cycle have not executed yet). The callback registration consists in setting the *cb_rtn* field to the callback routine to be called at the start of save or at the end of save. The *user_data* field can be set to the private data to be saved. All other fields are ignored. They are repetitive callbacks and remain until the end of the same simulation run or until there is a reset or a restart.

If time is requested via *vhpi_get_time()* during the *cbStartOfSave* *cbEndOfSave* or *cbStartOfRestart* callbacks, the time will be *T_c* from the previously completed simulation cycle.

vhpiCbStartOfRestart, vhpiCbEndOfRestart

A callback registered for reason `vhpiCbStartOfRestart` or `vhpiCbEndOfRestart` trigger when a restart command is processed by the tool. Please refer to the save and restart section of the foreign models chapter for more information on how these callbacks are used to restart foreign models or applications. The `vhpiCbStartOfRestart` callback occurs at the beginning of the restart of the VHPI models while the `vhpiCbEndOfRestart` callback occurs at the end of the restart operation. A model may not need to register for both callback reasons, but these two reasons are provided as a convenience to the user. For example, the user can use the first one to restore the foreign models private data and the `vhpiCbEndOfRestart` to re-register callbacks if necessary, since everything has been restored at this point. When `vhpiCbEndOfRestart` is called, the client is assured that all model instances that registered `vhpiCbStartOfRestart` have been initially processed. These callback registrations MUST happen during the save command in either of the `vhpiCbStartOfSave` or `vhpiCbEndOfSave` callbacks. The reason for that is that some information needs to be passed between the save action to the future restart action so that the foreign models can retrieve the correct saved data from the saved file (see save and restart of foreign models in Chapter 7). The callback registration consists in setting the `cb_rtn` field of the callback data structure to the callback function, the reason field to the `vhpiCbStartOfRestart` or `vhpiCbEndOfRestart` reason and the `user_data` field to an id identifying the location of the saved data. All other fields are ignored. That id is returned by the `vhpi_put_data()` function which saves data in the save file (see foreign models chapter). They are not repetitive callbacks. If time is requested via `vhpi_get_time()` during the `cbEndOfRestart` callback, the time will be the time of the saved data that is being restarted.

8.6 `vhpiCbStartOfReset`, `vhpiCbEndOfReset`

A callback registered for reason `vhpiCbStartOfReset` or `vhpiCbEndOfReset` triggers when a reset command is processed by the tool. The `vhpiCbStartOfReset` callback occurs at the beginning of the reset of the VHPI models while the `vhpiCbEndOfReset` callback occurs at the end of the reset operation. A model may not need to register for both callback reasons, but these two reasons are provided as a convenience to the user so that the user can use the first one to reset the state of the foreign models private data and the `vhpiCbEndOfReset` to set up new callbacks. The callback registration can happen at anytime during simulation. The callback registration consists in setting the `cb_rtn` field to the function to be called, and the callback reason to either `vhpiCbStartOfReset` and `vhpiCbEndOfReset`. When the `vhpiCbEndOfReset` triggers the current simulation time is 0 ns. Please refer to the reset section under the foreign models chapter for more information on the reset sequence. The execution of all `vhpiCbEndOfReset` callbacks is followed by the initialization phase 1.0.1 in the annotated simulation cycle. Therefore, all foreign model initialization code is re-executed as part of initialization. If time is requested via `vhpi_get_time()` during the `cbStartOfReset`, the time returned will be `T_c` from the previously completed simulation cycle. If time is requested via `vhpi_get_time()` during the `cbEndOfReset`, the time will be time 0.

Note: If simulation was restarted from time `Tn`, then reset sometime later, the current time after reset will become time 0 and, not `Tn`.

8.7 Callback function execution

The callback function specified by `cbDatap->cb_rtn()` is called when the condition (reason, time etc...) indicated by the callback registration becomes true and the callback is enabled. A callback is said to be triggered, and responds by calling the callback function.. The callback function is called with a single argument. The argument (`cbDatap`) is a const pointer to a `vhpiCbDataS` structure. This callback data structure is allocated by the VHPI server and is not the original callback data structure that was passed by the user at the registration of the callback. The argument `cbDatap` contains information about the callback and its current state that caused the routine to be invoked. The callback data structure contents should only be read by the client code and its contents including the handle denoted by the `obj` field are only valid for the duration of the callback function call. The handle provided is owned by the VHPI server and will not be the same handle provided by the user at the time of the registration. The client code must not release that handle.

1 During the callback routine execution, the access to the information model that is allowed is defined by the
2 semantics of the specific callback and the phase of execution of the tool . The callback routine is of return
3 type void.

4 The *user_data* field data may be provided at the registration of the callback, this field can be used to store
5 private data or handles for example. The *user_data* value at registration is returned in the *cbData*
6 parameter when the callback routine is executed.is preserved when the callback triggers. The *user_data* is
7 never referenced by the VHPI interface and its dereference is not required to be a valid memory address.

8 The *user_data* address will be constant for the life of the callback. The contents of that address can
9 however be changed by the client code

10 No memory allocated by the user is read or written to by VHPI when a callback executes. User memory
11 allocated at registration in a *vhpiCbDataS* is only read once when the callback is registered and is for
12 conveying intent and registering the callback.

15 **Procedural Interface References:**

16 See “*vhpi_register_cb()*” to register a callback.

17 See “*vhpiCbDataT*” for passing callback data information.

18 See “*vhpi_get_cb_info()*” to retrieve a callback.

19 See “*vhpi_remove_cb()*”to remove a callback.

20 See “*vhpi_enable_cb()*” to enable a callback.

21 See “*vhpi_disable_cb()*” to disable a callback.

22 See “*vhpi_put_value()*” to force, release or update a value.

23 See “*vhpi_get_value()*” to query an object value in various formats.

25 **Errors:**

27 **Restrictions:**

9. Value access and modification

This chapter describes how to access and modify values. This is one of the capabilities required to claim a compliance level of `vhpiCapabilitiesP` `tovhpiProvidesForeignModel` or `vhpiProvidesDebugRuntime`. This chapter defines the interface functions and associated data structures. Classes of objects that support value access will have a `vhpi_get_value()` operation defined (see information model), while those that support the modification of values will have a `vhpi_put_value()` operation defined. Additionally a function `vhpi_schedule_transaction` is defined to schedule a transaction on a driver of a signal. In order to do that, one must access the drivers of basic signals. If a signal is not a basic signal, one must first access its basic signals according to the semantics described in Chapter ? on Connectivity.

The value functions can be used directly on objects that are scalars or arrays of scalars. In order to access values of composites that are more complex than an array of scalars, users are expected to traverse the composite to the level of a scalar or an array of scalars before using the value functions defined by the interface.

The interface defines a value structure as the mechanism to pass values between a model or application and the tool supporting the VHPI interface. The value structure and related types are defined as follows :

```
typedef struct vhpiValues
{
    vhpiFormatT format;      /* IN/OUT: (depending on format) value
                             format */
    int bufSize;             /* IN: size in bytes of the buffer */
    vhpiIntT numElems;       /* IN/OUT: number of array elements in the
                             value,
                             undefined value for scalars */
    vhpiPhysT unit;          /* IN/OUT: physical position of the unit
                             in which the physical value is
                             expressed */

    union
    {
        vhpiEnumT enumv, *enumvs; /* OUT: enumeration */
        vhpiIntT intg, *intgs;     /* OUT: integer */
        vhpiRealT real, *reals;    /* OUT: floating point */
        vhpiPhysT phys, *physs;    /* OUT: physical */
        vhpiTimeT time, *times;    /* OUT: time */
        char ch, *str;             /* OUT: character or string */
        void* ptr, *ptrs; /* OUT: simulator representation value or access
                             value */
    } value;
} vhpiValueT;
```

The format values up to the `vhpiRawDataVal` format (included) are mandatory formats to be supported by `vhpi_get_value`, `vhpi_put_value` and `vhpi_schedule_transaction`. The types of the objects for which they can be used are described below. Other uses are undefined by the standard.

Implementations are free to enhance the set of supported formats. There is a standard defined format mapping to the type of the object which is supported by the functions `vhpi_get_value`, `vhpi_put_value`, `vhpi_schedule_transaction`. Other formats may be supported by the access value functions and `vhpi_format_value` but these formatting of values are not defined by the standard.

```
typedef enum
{
```

```

1     vhpiBinStrVal,
2     vhpiOctStrVal,
3     vhpiDecStrVal,
4     vhpiHexStrVal,
5     vhpiEnumVal,
6     vhpiEnumVecVal,
7     vhpiIntVal,
8     vhpiIntVecVal,
9     vhpiLogicVal,
10    vhpiLogicVecVal,
11    vhpiRealVal,
12    vhpiRealVecVal,
13    vhpiPhysVal,
14    vhpiPhysVecVal,
15    vhpiTimeVal,
16    vhpiTimeVecVal,
17    vhpiObjTypeVal,
18    vhpiCharVal,
19    vhpiStrVal,
20    vhpiPtrVal,
21    vhpiPtrVecVal,
22    vhpiRawDataVal
23
24 } vhpiFormatT;
25

```

The definitions of `vhpiEnumT`, `vhpiIntT`, `vhpiRealT`, `vhpiPhysT` and `vhpiTimeT` are expected to be defined by the simulation vendors with the following requirements mandated by the standard,

- `vhpiEnumT` should be at least 32 bits wide
- `vhpiIntT` should be at least 32 bits wide
- `vhpiRealT`, `vhpiPhysT` and `vhpiTimeT` should be at least 64 bits wide

The value data structure and any associated buffer to hold values of composites should be allocated and managed by the users of the functions `vhpi_get_value()`, `vhpi_put_value()`, `vhpi_schedule_transaction` and `vhpi_format_value()`. The following are the interpretations of the fields in the value structure,

format

The format in which the data is desired (`vhpi_get_value`) or supplied (`vhpi_put_value`, `vhpi_schedule_transaction`, `vhpi_format_value`). This should be specified by the users. There are format tuples, one for scalars and the other for array of scalars, associated with the basic data types of enumeration, integer, character, floating point, physical and time. For each mandatory format, there is a field in the value union. The format `vhpiStrVal` can be used to retrieve values of objects of type string, enumeration type or array of characters. The format `vhpiObjTypeVal` has been provided to obtain a value in its native form without requiring the user to find out the type of the object. The interface will determine the most appropriate format in this case and change the format field to reflect that format of representation of the value, while returning the value. The format `vhpiRawDataVal` has been provided from a performance standpoint, to enable implementations to return the simulator representation of the value.

Note : Though time types are physical types, the standard makes a distinction in keeping with possible future extensions requiring a representation for time different from physical types.

bufSize

This field should be set by the user to the byte size of the user allocated value buffer and is required for values of array types. The corresponding value field of the union should be set to point to the value buffer. The interface will check if the buffer size is sufficient to hold the value and `vhpi_get_value` will return the required size if it is not. Consequently the size in bytes required to represent a value will be returned by a call to `vhpi_get_value` when setting `bufSize` to 0. The field `bufsize` is IN and is always set by the caller.

Note : For string values, the buffer has to be at least as large as the length of the string incremented by one for string termination. The string value returned for objects of array of characters should not add surrounding double quotes; a termination character \0 will be added at the end of the string value. The numElems field will be set to be the real length of the character string (excluding the extra \0); The bufSize should be set by the caller who allocates the buffer string to be filled up to the byte length of the string +1 (accounting for the \0). For all other array types , the buffer should be at least as large as the number of elements in the array multiplied by the size of the element data type.

The above rules apply to any string value obtained with any string format (vhpiStrVal, vhpiBinStrVal, vhpiHexStrVal and vhpiDecStrVal).

numElems

This field is used only for representing values of array types and should be set to the number of array elements represented by the union value field of str, intgs, reals, times, physs or ptrs . For string types, it is set to the string length including the termination character. For all scalar types, this value is undefined.

unit

This field is used for value representation of time or physical types; *vhpi_get_value* will set this field to the physical position of the unit in which the returned value is represented for physical types. A physical value represented in a vhpiValueT value structure is defined by the value.phys field and the unit field such that the multiplication of value.phys by the unit field should provide the physical value scaled to the base unit of its physical type. The unit field can be set by the user for obtaining a physical value in any physical position of unit while using the VHPI function *vhpi_format_value*. *vhpi_put_value* should accept physical values of any physical position representation. The VHPI property *vhpiPhysPositionP* can be applied to a reference handle of a unit declaration (vhpiUnitDeclK) of a physical type to query the physical position of that unit declaration. The function *vhpi_get_phys* should be used to query the *vhpiPhysPositionP* property. The physical position of a physical literal of value integer 0 or floating point 0 is always 0.

If the unit is 1, the physical value(s) in value.phys(s) is(are) expressed in base units of the physical type.

value

This is defined to be a union, which contains the actual value of an object or expression. The following are the fields within this union,

1. **enumv**

This field should be used for the positional values of enumeration typed object. VHPI enumeration define constants are defined for the standard logic, bit and boolean types.

2. **enumvs**

This is a pointer field and should be used for arrays of enumeration types. This field should be set to point to a user allocated buffer.

3. **intg**

This field is used for values of integer typed objects.

4. **intgs**

This pointer field should be used for array of integers values. This field should be set to point to a user allocated buffer.

5. **real**

This field should be used for values of floating point typed objects

6. **reals**

This field should be used for values of arrays of floating point.

7. **phys**

This field should be used for physical type values.

8. **physs**

This field should be used for values of arrays of physical types.

9. **time**

This field should be used for values of TIME typed objects

10. **times**

This field should be used for values of arrays of TIME type.

11. **ch**

This field should be used for values of character types.

12. **str**

This field should be used for values of string type and string formatting. The interface defines a separate function, *vhpi_format_value()* for doing string value formatting for other typed objects. (9.2Formatting VHDL values).

13. **ptr**

This field should be used to get the simulator/tool representation of the value for any type (vhpiRawDataVal format) or to get the access value of a variable of an access type (vhpiPtrVal format).

The standard does not mandate any specific data representation, nor does it make it mandatory for vendors to publish their data representations. The lifetime of this value is unspecified by the standard.

14. **ptrs**

This field should be used to get the access values for arrays of access type elements (vhpiPtrVecVal format).

There are various objects in the information model that carry values that can be accessed using the VHPI value mechanism. The class kinds that support values operations are:

1. All sub-classes of the objDecl class: *vhpiConstDeclK*, *vhpiSigDeclK*, *vhpiFileDeclK*, *vhpiVarDeclK*, *vhpiGenericDeclK*, *vhpiPortDeclK*, *vhpiSigParamDeclK*, *vhpiVarParamDeclK*, *vhpiConstParamDeclK*, *vhpiFileParamDeclK*

Their value can be fetched if the object declaration has been elaborated and the property *vhpiAccessP* allows reading of the object value (*vhpiReadAccess* bit is set) . If the value is fetched at the end of elaboration, the value is the default ('left) or initial value from the initial expression of the object declaration (as defined by the elaboration of the object). The value of a generic after elaboration will be the value after generic propagation. During simulation, the value fetched is the value of the object at this particular time.

For a *vhpiFileDeclK*, the value is the logical name of the file. The value is of type string. The value is the string value supplied in the declaration if present or the logical name the file was associated with during a call to *FILE_OPEN* if the file was opened during simulation. If the file is not opened at the time of the query, a warning is generated and the value structure is not filled with a value. In this case, *vhpi_get_value* returns a negative value to indicate that the call failed.

For shared variables of protected types, *vhpi_get_value* must be called through a *vhpi_protected_call* which obtains a lock on the variable. For a variable of an access type, the access value can be fetched: the access value is the address of the allocated object, the format to be used is *vhpiPtrVal* and *vhpiPtrVecVal* for arrays of access type. The dereference value designated by the current access value of the variable can be fetched from a handle to the dereference object (*vhpiDerefObjK*) which is obtained after applying the *vhpiDerefObj* method to the variable handle. If the variable has an access value of 0 (null) it does not designate an allocated object, in that case it is an error to apply the *vhpiDerefObj* method (dereferencing a null pointer); the *vhpiDerefObj* method should return a null handle and an error should be generated. The access value designates the created access object (just like a pointer). This is different from the value of the object which can be fetched by dereferencing the object. The value of a dereference name (xyz.ALL) will be the dereference value pointed by the object xyz. The handle kind of a dereference name is *vhpiDerefObjK*. Values of dereference names can be fetched with the basic formats defined the value structure: for example, a dereference value of a variable of type access to integer can be fetched with the *vhpiIntVal* format. The default value of a variable of an access type is NULL (NULL pointer). The initial access value of a variable with an initial expression will be the access value of the initial expression. A dereference object (*vhpiDerefObjK*) has a value.

For foreign subprogram calls, it is possible to get the actual values associated with the formal parameters if the mode of this parameter is either IN or INOUT (value can be read). For signal subprogram parameters, the value fetched is the effective value of the signal. In order to fetch the driving value, a handle to the

driver must be obtained. Subprograms are dynamically elaborated therefore the values of their parameters or declared items can only be fetched when the program is currently executing or is suspended. We provide a method to get the current executing region (*vhpiCurRegion*) and a method to access the stack of an equivalent process (*vhpiCurStack* see subprogram call class diagram). The user can only fetch the values of parameters or declared items in a subprogram call if the subprogram call is either executing or is on the call stack of the current executing process or subprogram, or is a suspended process or on the stack of a suspended process.

For port or signal declarations (*vhpiPortDeclK*, *vhpiSigDeclK*), the value fetched is the effective value. For the in part of an inout port (*vhpiInPortK*), or for an inout mode port, the value fetched is the effective value; for the out part of an inout port (*vhpiOutPortK*), the value fetched is the driving value.

2. Any sub-class of the class name and class literal has a value (*vhpiIndexedNameK*, *vhpiSliceNameK*, *vhpiSelectedNameK*, *vhpiAttrNameK*, *vhpiDerefObjK*).

The mechanism is exactly the same for the name sub classes as for the sub classes of the *objDecl* class. It is not possible to fetch directly the value of any other expression or function call. *vhpi_get_value* should support getting values of locally static names; an implementation may optionally provide support for globally static names.

There is the possibility of getting a value for handles of any of the sub-classes of class literal. The standard defines a more convenient mechanism using properties for each sub-class of the class literal: *vhpiIntValP* for class *vhpiIntLiteralK*, *vhpiRealValP* for class *vhpiRealLiteralK*, *vhpiPhysValP* for *vhpiPhysLiteralK* and *vhpiStrValP* for classes *vhpiStringLiteralK*, *vhpiBitStringLiteralK*, *vhpiCharLiteralK* and *vhpiEnumLiteralK*.

3. Simulation objects:

A driver (*vhpiDriverK*) has a value which is its current driving value. This driving value can only be fetched after simulation initialization phase has been completed. [See PA046](#). The driving value of a driver reflects the value of the last matured transaction.

Values can be fetched after simulation initialization has completed in a simulation session, or after elaboration in an elaboration session.

9.1 Accessing VHDL object values

```
(PLI_INT32T) vhpi_get_value(vhpiHandleT refHdl, vhpiValueT* valuep)
```

The interface defines a function *vhpi_get_value* for getting values. The first parameter, *refHdl* represents the handle to the object of which the value is required. The second parameter is a user allocated value structure. This structure should have the format field set by the user based on the VHDL type of the object referenced by *refHdl*. For a description of the formats allowed for each VHDL basic type, see the value structure description.

For scalar type object values, the interface copies the value into one of the scalar fields in the value union within the value structure. For arrays of scalars, the users should allocate a buffer large enough to hold the value and place the pointer to this allocated buffer into an appropriate pointer field in the value union within the value structure. The interface then copies the value into the allocated buffer. *vhpi_get_value* will not return a partial value.

Values can be accessed for all the classes of objects that possess values (that support the *vhpi_get_value* operation in the information model), which includes the set of classes outlined in 9.1 above.

9.2 Formatting VHDL values

A function `vhpi_format_value` is provided to change the representation of a value in a different format. This function takes two value pointers, the first one is the input value, the second one is the output value. The first value contains the value in a given format, the second value structure should have:

- the **format** field set to the requested format,
- the **bufSize** field set to size of the user allocated buffer (if formatting values requires the allocation of a buffer),
- the **unit** field set to the physical unit position for time or physical type unit conversions.
- the **union** field which corresponds to the requested format set to point the user allocated buffer.

This function can be used to format value into non native format representations as defined by the vendor or to do unit scaling for time or physical types. If specified, handle to the type corresponding to the value. If null it may limit the conversions which are possible.

9.3 Updating VHDL object values

The class of objects that support runtime modification of values is a subset of the class of objects that support fetching values. `vhpi_put_value` can be used during simulation to change the value of objects which possess the `vhpi_put_value` operation, or during elaboration to set the initial driving value of a foreign driver, the initial value of signals, ports or shared variables of a foreign architecture or the return value of a foreign function. See PA047. There are two types of update: deposit or force. Both can be applied with or without propagation of the value. Five update flags are defined; `vhpiDeposit`, `vhpiDepositPropagate`, `vhpiForce`, `vhpiForcePropagate` and `vhpiRelease`. Another flag `vhpiSizeConstraint` is also available to set the constraint of an object of an unconstrained type. Propagation of the value is only meaningful for signal class of objects. `vhpiForcePropagate` and `vhpiDepositPropagate` are identical to respectively force and deposit for objects which do not belong to the signal class. `vhpi_put_value` can be called at any point during initialization and simulation and additionally during elaboration for setting the return value of foreign functions.

The valid object classes for immediate update are:

1. Subclasses of the `objDecl` class: `vhpiSigDeclK`, `vhpiVarDeclK`, `vhpiPortDeclK`, `vhpiOutPortDeclK`, `vhpiSigParamDeclK`, `vhpiVarParamDeclK`

Objects of class `vhpiConstDeclK` and `vhpiFileDeclK` cannot be modified using `vhpi_put_value`. The behaviour of `vhpi_put_value` on a `vhpiGenericDeclK` is unspecified by the standard. The exception to this rule is with the use of VHDL functions that have a foreign C implementation. These functions can be used in initialization expressions, and hence can be used indirectly to set the values of these classes of objects.

Parameters to subprograms can be modified only if their mode is either `vhpiOut` or `vhpiInOut`.

Immediate update can apply to GUARD signals. Direct update of implicit signals such as signal attributes is not permitted. If an event is created for a signal, its implicit signals such as the signal attributes are updated in the signal evaluation phase as a result of the corresponding signal being updated. Similarly guarded signals assignments can be triggered as a result of the GUARD signal becoming true.

Ports of all modes support modification of their value. For ports of mode `vhpiOut` and for `vhpiOutPortK` (out part of an inout port) and or signal parameter of mode `vhpiOut` or `vhpiOutSigParamK` (out part of an INOUT sigPamDecl) this operation shall be equivalent to changing the port driving value. Similarly, modification of the values of subprogram signal parameters which are of mode `vhpiOut` shall be equivalent to changing the driving value of the actual. For port of other modes or `vhpiInPortK` (in part of an INOUT port), or `vhpiInSigParamK` (in part of an INOUT sigParamDecl) or `vhpiSigDeclK`, the value that is modified is the effective value.

Deleted: only

Formatted: Font: Italic

Deleted: on a runtime model

Immediate update on shared variable of protected types must be accomplished through a *vhpi_protected_call* which acquires the lock on the variable, otherwise an error should be generated. The behaviour of *vhpi_put_value* is unspecified for shared variables of non protected types.

2. Subclasses of the class name : *vhpiIndexedNameK*, *vhpiSliceNameK*, *vhpiSelectedNameK*, *vhpiDerefObjK*.

vhpi_put_value shall not be used on prefixed names that are derived from *vhpiConstDeclK* as also subclasses of the class *vhpiLiteralK*.

The rules and restrictions stated in paragraph 1 for object decls also stand for sub-elements of these objects.

3. Function call handles: *vhpiFuncCallK*

The return values of function calls can be set by depositing a value on the function call object handle. Setting the return value for foreign functions is required by the standard. Setting the return value with *vhpi_put_value* of VHDL functions (overriding the returned VHDL value) is a legitimate vendor extension which is not defined by the standard.

If the return type of a function call is a composite type more complex than an array of scalars, the caller shall iterate over the sub-elements of the return type and call *vhpi_put_value* on each of these. The iterations on indexedNames and selectedNames are ordered iterations defined by the aggregate rule in the VHDL LRM 1076-2001.

Setting the return value of an unconstrained function shall be done by first calling *vhpi_put_value* to set the number of elements of the unconstrained function return parameter. The **numElems** field of the value data structure shall be set to the total number of elements of the returned array type. The values of the other fields of the value structure are unspecified. The flag parameter of *vhpi_put_value* shall be set to *vhpiSizeConstraint*. Then a second call to *vhpi_put_value* will modify the returned value by passing the actual value to be returned. A runtime error shall be generated if the size of the value in the second *vhpi_put_value* call does not match the size specified in the previous *vhpi_put_value* call. Same mechanism applies if a function returns a record type which one of the record elements is an unconstrained array.

From a subprogram call handle, users can traverse the call stack and access subprogram variables. The values of these variables can be modified. All local variables that are on the call stacks of the currently executing process or subprograms can also be modified.

4. Driver handles: *vhpiDriverK*

Drivers can have their current driving value read but ~~and updated with respectively *vhpi_get_value* and *vhpi_put_value*. An additional function *vhpi_schedule_transaction* provides the functionality comparable to a VHDL simple signal assignment statement; the function can schedule a transaction with zero or non zero delay, a mode of transport or inertial and a optional pulse rejection limit.~~

The semantics of the update flags:

The modification of variable values and returned values of function calls always takes immediate effect. For a variable, the flags *vhpiDepositPropagate*, and *vhpiForcePropagate* have the same effect as respectively the *vhpiDeposit* and *vhpiForce* flags. For a function call, *vhpiDepositPropagate*, *vhpiForcePropagate* and *vhpiForce* have the same effect as *vhpiDeposit*. *vhpiRelease* has no effect on function call handles. The behavior of *vhpi_put_value* with the *vhpiForce* flag is unspecified for shared variables of non protected types. For shared variables of protected type, any immediate update must be done through a *vhpi_protected_call*, an error should be generated if an immediate update is attempted outside of a *vhpi_protected_call*. The modification of signal and port values has special semantics and are described in the following paragraphs. The terms signal and port are used to denote the general class of objects which are either signal or port declarations or the out side of inout port declarations, or sub-element of these. All modes can be applied to update the value of a port or signal kind of object.

The interface supports four different modes of updating the values of signals and ports,

Deleted: not written

Formatted: Font: Italic

Formatted: Font: Italic

Formatted: Font: Italic

Deleted: . In order to change the current driving value of a driver, the mechanism is indirect through the use of the interface function *vhpi_schedule_transaction*.¶

1. Depositing a value without propagation for the current cycle
2. Depositing a value with propagation for the current cycle
3. Forcing a value without propagation until release
4. Forcing a value with propagation until release

The following enumeration type defines the set of flags that can be used while updating the values of signals and ports

```
typedef enum
{
    vhpiDeposit,
    vhpiDepositPropagate,
    vhpiForce,
    vhpiForcePropagate,
    vhpiRelease,
    vhpiSizeConstraint
} vhpiPutValueModeT;
```

The following is a description of these flags,

vhpiDeposit

- The value is deposited but not placed on hold. There is no propagation through the signal network. If this happens at the beginning of a cycle or during network propagation (after a.1.0 but before d.0.1), the value could be overwritten through VHDL signal update or network propagation.
- If this happens after network propagation and before process execution (after c.1.0 but before d.1.0), all readers of this signal will see the new value for the current cycle but the signal network may be inconsistent.
- If the value is deposited during process execution (after d.0.1), there is no guarantee on whether all readers will see the same value in the current cycle. This last feature is non-portable.

vhpiDepositPropagate

The value is deposited with propagation. The value is not placed on hold. This form of update will be effective for the current cycle alone and can be done with the following semantics in the various phases of a given simulation cycle,

Beginning of a cycle (after a.1.0 but before b.1.0)

In this case the value is deposited and propagated in the same cycle.

Callback reasons that can be used to stop at the beginning of a cycle are :

- vhpiCbNextTimeStep (a.1.1)
- vhpiCbStartOfNextCycle (a.2.1)
- vhpiCbAfterDelay (a.2.2)

During or after network propagation but before VHDL process execution (after a.2.2 but before d.1.0)

In this case VHPI will introduce a new delta cycle, in which the value change with propagation takes effect. The value is not changed for the current delta cycle.

Callback reasons that can be used to get to this part of the simulation cycle :

- vhpiCbValueChange (after a.2.2 but before d.0.1)
- vhpiCbStartOfProcesses (foreign models execute) (d.0.1)

During non-postponed process execution (after d.0.1 but before f.1.0)

The interface introduces a new delta cycle, within which the value is updated with propagation. The value is not changed for the current cycle.

Callback reasons that can be used to get to this part of the simulation cycle :

- `vhpiCbResume` (after d.0.1 but before d.1.0)
- `vhpiCbStm` (after d.0.1 and before d.1.0 but after `vhpiCbResume`)
- `vhpiCbSuspend` (during e.1.0 and before e.1.1)
- `vhpiEndOfProcesses` (e.1.1)
- `vhpiCbLastKnownDeltaCycle` (f.1.1)

During and after postponed process execution (after g.1.0 through the rest of the simulation cycle)

It is an error to deposit a value with propagation at this stage. This stage includes postponed process execution.

Callback reasons that can be used to get to this part of the simulation cycle :

- `vhpiCbStartOfPostponed` (g.1.1)
- `vhpiCbEndOfTimeStep` (h)
- `vhpiCbQuiescence` (after h)

vhpiForce

- The signal or port value is forced and placed on hold until release. There is no propagation. VHDL signal updates or network propagation cannot overwrite the value. The value will remain on hold, until released using `vhpi_put_value` with the `vhpiRelease` flag. Another force can be applied on an already forced value.
- If this happens before process execution (before d.1.0), all readers of the signals or ports will see the forced value.
- If this happens during process execution, not all readers of the signal or port are guaranteed to see the new value. This mode of usage will be non-portable.

vhpiForcePropagate

This flag can be used to achieve the same effect as `vhpiDepositPropagate`, with the added consequence of the value being placed on hold, until the user releases the hold using the `vhpiRelease` flag. VHDL signal updates or propagation will not overwrite the value as the value is put on hold with the force. Another force can be applied on an already forced value, which replaces the previously forced value

The semantics with respect to the various phases of a simulation cycle are precisely the same as with `vhpiDepositPropagate`.

Immediate update with `vhpiDepositPropagate` or `vhpiDeposit` during network propagation has an indeterminate result and is not portable. Immediate update with `vhpiForce` or `vhpiForcePropagate` have a determinate result for the signal that is forced but the network may be inconsistent with respect to the model.

- The integer property `vhpiIsForcedP` can be used to query if the object value is forced.

vhpiRelease

- This flag can be used to release the hold placed by a force. An object value can be placed on hold using one of `vhpiForce` or `vhpiForcePropagate`. The hold can be released using `vhpiRelease`. After the value has been released, the object value can be updated through VHDL signal update or network propagation (it does not revert to the value prior to the force).
- `vhpiRelease` has only the effect of releasing the value of objects for which the `vhpiProperty` `vhpiIsForcedP` is TRUE.

- The pointer to the value structure `valuep` is not required when `vhpi_put_value` is called with the `vhpiRelease` flag. If a non null `valuep` pointer is provided, it will be ignored.

Formatted: Bullets and Numbering

Formatted: Indent: Left: 0.25"

vhpiSizeConstraint

- `vhpi_put_value` can be used with this mode to set the constraint of the reference handle if the type of the reference handle is unconstrained. A subsequent call to `vhpi_put_value` will update the value of the reference handle. An error should be generated if the size constraint indicated by the first call does not match the size of the value in the second `vhpi_put_value` call.

It should be noted that VHDL subprograms that have a VHPI foreign attribute can be executed at any point in a simulation cycle, which implies that the users will have access to values and can update values virtually at any point during signal update, network propagation and process execution. The semantics described under the various flags apply for these instances of value modification.

Further, any value change callbacks registered on signals, ports will be triggered when the user **updates their value and creates an event** using either `vhpiDepositPropagate` or `vhpiForcePropagate`. Using `vhpiDeposit` or `vhpiForce` on signal and ports will not involve triggering of any value change callbacks. Also, callbacks registered on signals and ports with reason `vhpiCbForce` will be triggered when the signal or port is forced using the interface. Similarly, all callbacks registered on signals and ports with reason `vhpiCbRelease` will be triggered when the signal or port is released using the `vhpiRelease` mode through the interface. Value change callbacks for variable trigger whenever the value of the variable has changed.

A deposit value has no effect if the object is forced. A forced signal can be forced to a new value, the last force takes effect. A release has no effect other than on a forced object.

`vhpiCbForce` or `vhpiCbRelease` callbacks trigger only if the force or release occurs.

informative note: a warning may be generated by an implementation if `vhpi_put_value` has no effect.

If `vhpi_put_value` detects a range constraint violation between the value and the target object, `vhpi_put_value` shall generate an error for range constraint violation if such a case is detected; that error can be checked immediately by calling `vhpi_check_error`.

informative note: the detection may occur later and be reported in an error cbk.

9.4 Scheduling transactions on signal drivers

```
(PLI_INT32T) vhpi_schedule_transaction(vhpiHandleT refHdl,
                                     vhpiValueT* valuep, PLI_INT32T numValues, vhpiTimeT*
delayp,
                                     PLI_UINT32 delayMode, vhpiTimeT* pulseRejp)
```

The interface provides a capability to schedule transactions on drivers. The function to use is `vhpi_schedule_transaction`, which has the above signature. The following are the parameters that should be passed to this function,

1. **refHdl**
This is a VHPI handle that represents an object that supports value scheduling.
2. **valuep**
This is a pointer to a single value structure or an array of value structures.
3. **numValues**
This field is used to specify the number of values that are being passed through the value structure pointer, `valuep`.
4. **delayp**
This is the delay, always with respect to the current simulation time, that will be used in processing the scheduling operation.

1 5. **delayMode**

2 This represents the delay mode, which could be one of *vhpiInertial* or *vhpiTransport*.

3 6. **pulseRejpt**

4 This is a pulse rejection limit that can be specified. If the desire is to have an inertial delay without a
5 pulse rejection limit, this field should be set to null.

6
7 The reference handle should be either a handle to a driver, of type *vhpiDriverK*, a handle to a VHPI driver
8 collection, of type *vhpiDriverCollectionK*.

9
10 The drivers returned by the interface will always be drivers to basic signals. A basic signal is either a scalar
11 signal or a resolved composite typed signal. A collection of drivers to basic signals can be constructed
12 using the VHPI call *vhpi_create* and used to schedule updates collectively to all the drivers in the
13 collection. A collection of drivers can be created only for the same unresolved composite typed signal.
14 Drivers driving parts of different signals cannot be placed in the same driver collection.

15
16 For a driver to a scalar signal, a single value structure should be passed with the format set to indicate a
17 scalar value. For collections of drivers or for a composite driver, the following rules, based on the type of
18 the driven signal, should be used to associate value structures with driver transaction values for scheduling,
19

- 20 • When the type of a signal is an unresolved array of scalars, a collection of drivers can be created to
21 one or more of the scalar sub-signals, when the type of a signal is a resolved array of scalars, a single
22 composite driver handle should be used to schedule a transaction. In either cases, a single value
23 structure should be passed with a format being a vector format, with an allocated value buffer having
24 as many scalar values as the number of scalars. In the case of a driver collection, the *numElems* field
25 of the value structure should be equal to the *numMembers* property of the collection and in the case of
26 a composite driver, it should be equal to the number of scalars. The *numValues* parameter should
27 always be 1.
- 28 • When the type of a signal is either an array of composites or a record, an array of value structures
29 should be passed, whether we have a single composite driver or a collection of drivers. The value
30 structures should be passed at the coarsest granularity possible. This implies that for all subsignals of
31 the composite signal, which are arrays of scalars, the value has to be passed as a vector for all the
32 scalars. For all other subsignals, the same rule should be used recursively, down the type hierarchy.
33 All value structures passed can only be either values to scalars or arrays of scalars.

34
35 The following table describes the relationship between signal subtypes, drivers, and the value structures
36 required to be passed.

37
38
39
40

Signal subtype	Driver or Collection handle that can be used to schedule transactions. Note: it is possible to not get any drivers if the signal is not driven	Example	Number of value structures	Description of value structures
Unresolved scalar	0..1 scalar driver <ul style="list-style-type: none">A scalar driver handle.	BIT	1	Single value structure with the format set to an appropriate scalar format.

Resolved scalar	* scalar drivers. A scalar driver handle.	STD_LOGIC	1	Single value structure. <ul style="list-style-type: none"> Scalar format and value for a driver handle
Unresolved composite	0..1 driver for each basic signal in the composite signal. <ul style="list-style-type: none"> A driver handle to one of the basic signals A collection of drivers to one or more basic signals. 	STD_LOGIC_VECTOR	1	Single value structure. <ul style="list-style-type: none"> Scalar format for a single driver handle Vector format for a collection of driver handles
Resolved composite	* composite drivers <ul style="list-style-type: none"> A composite driver handle. 	RECORD WITH N SCALAR FIELDS	N	N value structures with scalar formats, one per field
		RECORD WITH N SCALARS AND M VECTORS OF SCALARS	M+N	Array of value structures, <ul style="list-style-type: none"> N value structures with scalar formats, one per scalar field. M value structures with vector formats, one per vector field.

The layout of value structures passed adhere to the following rules:

- For all composite drivers, the value structures passed in should be in the same order as the declaration order in the typemark of the resolved subtype.
- For all collections of drivers, the value structures passed in should be in the same order as the sequence in which drivers were added to the collection, with Rule 1 applying, whenever we find a driver for a resolved composite in the collection. Can we have a collection of collection of drivers?

The vhpCbTransaction callback reason is provided to be able to access the time/value pair of a transaction. The callback is registered on the driver or signal handle and triggers when a transaction matures.

A single value structure cannot be used to get the current driving value of a driver collection or a composite driver which is not an array of scalars. The only mechanism is to iterate over all the individual drivers and get their values.

A driver or a set of drivers can be disconnected with *vhpi_schedule_transaction()*, by posting a NULL transaction. The drivers involved in a request to disconnect using *vhpi_schedule_transaction* should be drivers corresponding to guarded signals assigned by sequential signal assignments. Using *vhpi_schedule_transaction* to post a NULL transaction to other type of drivers is undefined by the standard. Vendors may choose to extend the functionality defined by the standard by allowing scheduling of NULL transactions on drivers corresponding to guarded concurrent signal assignment statements to guarded signals. In this case the behavior of the driver on posting a NULL transaction will be specified by the vendor tool.

Issue on disconnecting guarded signals.

Any guarded signal which is disconnected using *vhpi_schedule_transaction* can be reconnected, either using *vhpi_schedule_transaction*, by posting a non-NULL transaction, as with a valid set of value structures, or through VHDL, when a guard expression becomes TRUE and a non-NULL signal assignment takes effect.

At a given point in time, there can be only one active disconnection scheduled for a driver through VHPI or VHDL?.

The disconnection of drivers can also be done using *vhpi_schedule_transaction* on procedure OUT mode signal parameters, as long as the actual is a guarded signal (why guarded signals). The same restrictions as noted above apply in this case as well.

A transaction scheduled with zero delay will take effect in the next delta cycle. Such zero delay transactions can be posted:

- a) during non-postponed process execution
- b) in a vhpi callback function which was registered for reasons:
 - i) *vhpiStartOfProcesses*
 - ii) *vhpiCbStmt*,
 - iii) *vhpiCbResume*
 - iv) *vhpiCbSuspend*
 - v) *vhpiCbSensitivity*
 - vi) *vhpiCbTimeOut*
 - vii) *vhpiCbRepTimeOut*
 - viii) *vhpiEndOfProcesses*
 - ix) *vhpiLastKnownDeltaCycle*

It shall be an error to post zero delay transactions at any other time. *vhpi_schedule_transaction* for non zero delay transaction can be called at any of a) and b) and additionally during postponed process execution.

10. Utilities

10.1 Getting current simulation time

```
(PLI_VOID) vhpi_get_time(vhpiTimeT * time_p, long *cycles_p)
```

This function shall get the current simulation time. The caller must allocate a structure of type *vhpiTimeT* and pass a pointer to this structure to the function. The time will be returned in the simulation time precision. If the users require the conversion of the returned time value in other units, they should use the interface function *vhpi_format_value*. The simulator time unit precision can be retrieved with the property *vhpiPrecisionP*. This property returns the physical position of the unit of the standard TIME type which

represents the minimum time unit precision of the tool (simulator). This property can be also used to interpret the unit in which time values are returned in callback time fields.

If the *time_p* parameter is set to NULL, then this function returns the absolute number of simulation cycles from start of simulation, through the second parameter.

If the *time_p* parameter is not NULL, then this function returns the current simulation time through *time_p* and the relative number of delta cycles that have been executed within the current simulation time step through the second parameter.

If the second parameter is NULL, then the relative or absolute delta cycle information is not returned. Further, the second parameter if non NULL, should be the address of an integer type at least 64 bits wide.

Procedural Interface References:

Use “*vhpi_get_phys(vhpiPrecisionP, NULL)*” to access the simulator precision of TIME values.
See *vhpi_user.h* file for the constant value definitions of the type and unit field.

10.2 Printing

10.2.1 Printing to the stdout, log files, displaying messages

```
(PLI_INT32T)vhpi_printf(const PLIBYTE8 * *format,...);
```

This function allows a VHPI application to send messages to the output files defined by the tool.

10.3 Error checking and handling

```
(PLI_INT32T) vhpi_check_error(vhpiErrorInfoT *errorp);
```

This function can be called to determine if the last previous VHPI function call had an error. It can either check if an error occurred or retrieve detailed error information. *vhpi_check_error()* takes an argument (pointer to error structure) and returns 0 if no error, or 1 if an error occurred.

If the parameter *errorp* is non null and if the previous VHPI call generated an error, the error information structure pointed out by *errorp* will be filled up on the return with the last error information. The error information structure must be allocated by the caller.

If 0 is returned, the error information structure field are meaningless. The message string is a static string buffer which contains the formatted error message. The error message is only valid until the the next VHPI function call.

File and line information are optional fields that can indicate for example the foreign model instance which caused the error, or the VHDL item from where an error originated. (see example in the functional reference). The error information is NOT persistent. The internal error information structure is static.

A tool flag could enable or disable the display of all VHPI errors to STDERR, STDOUT or LOG file. The configuration of which files to send the VHPI errors should be specified at the initialization (bootstrap/registration phase) of the VHPI interface. Need for a special function ? (Refer to section 8.4Printing messages).

Filtering of some errors can be performed via the registration of an error handler callback function. Such a callback must be registered for reason *vhpiCbPLIError*. (Refer to the callback chapter).

NOTE: Error messages may be printed to STDERR or LOG file. The number of errors displayed is not related to how many calls to *vhpi_check_error()* are in the code but to the number of errors generated by VHPI function calls that are not filtered out by the error handler.

1 *vhpi_check_error()* allows the user to check for VHPI errors and eventually take actions regarding certain
2 types of error.
3 The error information structure is used for building the error message that can be printed to the screen and
4 log file and is used by the *vhpi_check_error()* function.
5 Such an error message could look like:
6 VHPI: <vendor specific ERRCODE>: <message>
7 [*<file>* *<line>*]

8 **10.4 Tool control**

9 The VHPI functions *vhpi_assert()*, *vhpi_control()* can be called to affect the execution control flow.

11. Procedural Interface Reference manual

11.1 *vhpi_assert()*

vhpi_assert()			
Synopsis:	Raise an assertion		
Syntax:	vhpi_assert(severity, formatmsg, ...)		
Type		Description	
Returns:	int	0 on success, 1 on failure	
Type		Name	Description
Arguments:	vhpiSeverityT	severity	The severity of the assertion
	const PLI_BYTE8 *	formatmsg	The assertion message
		g	

vhpi_assert() shall be equivalent to the execution of a VHDL report statement. The function shall return 0 on success and 1 on failure. The function takes a variable number of arguments. The first argument, *severity*, shall be a value corresponding to one of the VHDL severity levels: *vhpiNote*, *vhpiWarning*, *vhpiError*, *vhpiFailure*. The second argument, *formatmsg*, is the formatted assertion string that gets printed. The formatted string shall use the same formats as the C printf functions. It is possible that a *vhpi_assert()* call causes the simulation to stop in the same way that a VHDL assert statement would do.

Example:

```

int check_clock_signal(scopeHdl)
vhpiHandleT scopeHdl; /* a handle to a scope */
{
    vhpiHandleT clkHdl;
    vhpiValueT value;

    /* look up for a VHDL object of name clk at the scope instance */
    /* get a handle to the clk named object */

    clkHdl = vhpi_handle_by_name("clk", scopeHdl);
    if (!clkHdl) return 1;
    value.format = vhpiLogicVal;
    vhpi_get_value(clkHdl, &value);
    if (value.logic == vhpiBit0) {
        vhpi_assert(vhpiError, "clock not high: %d", value.logic);
        return 1;
    }
}
return 0;

```

11.2 vhpi_check_error()

vhpi_check_error()			
Synopsis:	Retrieves information about a VHPI function error		
Syntax:	vhpi_check_error(errp)		
Type		Description	
Returns:	int	0 if no error, non zero if an error had occurred.	
Type		Name	Description
Arguments:	vhpiErrorInfoT *	errp	NULL or pointer to a structure containing error information
Related functions:	See each VHPI function for related standard or vendor specific error codes.		

vhpi_check_error () shall check if the last previous call to a VHPI function had caused an error. The function shall return 0 if no error occurred or non zero if an error had happened. If the error detailed information is not needed, NULL can be passed to the function. If the errp is non null, the error information structure to which it points to will be filled up with the error information. The error information structure must be allocated by the caller.

If 0 is returned (no error was detected), all field values are meaningless. The *severity* field indicates the severity level of the error. The *message* field is a pointer to a static buffer of the formatted error message. This error message string may be overwritten by subsequent calls to **vhpi_check_error()**. The *str* field can be used for various purposes: either to put a mnemonic string abbreviation of the error, or the name of the vendor product where the error originated. The *file* and *line* fields are optional fields and respectively indicate the VHDL file name and line number corresponding to a VHPI handle from where the error originated. In the case where the file and line number cannot be provided, these fields should respectively be set to null and -1.

```
typedef struct vhpiErrorInfoS {
    vhpiSeverityT severity; /* the severity level of the error */
    char          *message; /* the error message string */
    char          *str;     /* vendor specific string */
    char          *file;    /* Name of the VHDL file where the VHPI
                           error originated */
    int    line;           /* line number in the VHDL file of the
                           item related to the error */
} vhpiErrorInfoT;
```

```
typedef enum {
    vhpiNote = 1,
    vhpiWarning = 2,
    vhpiError = 3,
    vhpiFailure = 4,
    vhpiSystem = 5,
    vhpiInternal = 6
}
```

```
} vhpiSeverityT ;
```

Example 1:

```
vhpiErrorInfoT err;

if (!vhpi_check_error(&err))
    /* continue VHPI code */
else switch (err->severity)
{
    case vhpiError:
    case vhpiFailure:
    case vhpiInternal:
        return;
    case vhpiSystem:
        if (errno == ...)
            return;
    default:
        /* examine and decide if need termination */
        ...
}
```

Example 2:

```
1  entity top is
2  end top;
3  architecture my_vhdl of top is
4      constant val: integer:= 0;
5      signal s1, s2, s3: BIT;
6  begin
7      u1: C_and(s1, s2, s3);
8      process (s1)
9          variable va: integer:= val;
10         begin
11             va = myfunc(s1);
12         end process;
13 end my_vhdl;

/* hdl is a handle to the root instance */
void traverse_hierarchy(hdl)
vhpiHandleT hdl;
{
    vhpiHandleT subHdl, itr, duHdl;
    vhpiErrorInfoT err;

    itr = vhpi_iterator(vhpiInternalRegions, hdl);
    /* if error code is > 0 do not continue */
    if (vhpi_check_error(NULL)) return;

    if (itr)
    while (subHdl = vhpi_scan(itr)) {
        duHdl = vhpi_handle(vhpiDesignUnit, subHdl)
        if (vhpi_check_error(&err) > 0)
        {
            if (err->severity > vhpiWarning)
                if (err->file != NULL)
                    vhpi_printf("An error occurred during call to
                                traverse_hierarchy
                                at filename %s line %d\n",
                                err->file, err->line);
```

```

1      else
2          vhpi_printf("An error occurred during call to
3                      traverse_hierarchy\n");
4      return;
5  }
6  switch (vhpi_get(vhpiKindP, subHdl)) {
7      ...
8  }
9  }
10 }
11
12 The following error will be generated and displayed because the internal
13 region of a process kind does not have a 1-to-1 method to the bound
14 designUnit.
15
16 An error occurred during call to traverse_hierarchy at file myvhd1.vhd
17 line 8
18
19

```

11.3 vhpi_compare_handles()

vhpi_compare_handles()			
Synopsis:	Compare two handles to determine if they reference the same object		
Syntax:	vhpi_compare_handles(hdl1, hdl2)		
	Type	Description	
Returns:	int	1 if the two handles refer to the same object, 0 otherwise	
	Type	Name	Description
Arguments:	vhpiHandleT	hdl1	Handle to an object
	vhpiHandleT	hdl2	Handle to an object

vhpi_compare_handles () allows to determine if two handles are equivalent. Handle equivalence cannot be done with the C '==' comparison operator.

Example:

```

vhpiHandleT find_clock_signal(scopeHdl)
vhpiHandleT scopeHdl; /* a handle to a scope */
{
    vhpiHandleT sigHdl, clkHdl, itrHdl;
    int found = 0;

    /* look up for a VHDL object of name clk at the scope instance */
    /* get a handle to the clk named object */

    clkHdl = vhpi_handle_by_name("clk", scopeHdl);
    itrHdl = vhpi_iterate(vhpiSigDecl, scopeHdl);
    while (sigHdl = vhpi_scan(itrHdl)) {
        if (vhpi_compare_handles(sigHdl, clkHdl))
        {
            found = 1;
            break;
        }
        else vhpi_release_handle(sigHdl);
    }
    vhpi_release_handle(itrHdl);
    if found
        return(sigHdl);
    else return(NULL);
}

```

11.4 vhpi_control()

vhpi_control()			
Synopsis:	Send a control request to the tool		
Syntax:	vhpi_control(command, ...)		
	Type	Description	
Returns:	int	0 on success, 1 on failure	
	Type	Name	Description
Arguments:	int	command	The command request
	-	varargs	Variable number of command specific arguments

vhpi_control() provides some control capabilities over the tool. The argument *command* specifies the command request. The following command constant values are defined by the standard: *vhpiStop*, *vhpiFinish* and *vhpiReset*. A tool may also define some specific commands and define additional command constants which require some command specific arguments specified as *varargs*. Such commands can be used to pass information from VHPI user function to the tool. All commands are queued and executed at a "safe point" by the tool. I030: Francoise provide more precise definition of the safe point. *vhpiFinish* should not cause the tool to return to the host environment but rather cause the tool to reach the *vhpiEndOfSimulation* point.

If multiple calls to *vhpi_control* are made in sequence, they should be all queued. Further the standard commands reset, stop and finish are executed in the order they were queued. Other vendors commands may be queued (some may not require queueing) and the order is unspecified in the order in which they are executed by the tool. (Basically it is left to the tool to decide what to do on its vendor specific commands).

If the argument value is set to *vhpiStop*, after returning from the VHPI user code, the simulator will stop.

If the argument value is set to *vhpiFinish*, it would request the simulation to finish the execution of all scheduled events in the current delta cycle but not to exit. The C user function continues execution even after the *vhpi_control()* until it returns control to the simulator.

If the argument value is set to *vhpiReset*, upon return of the VHPI user function, the simulator will execute the sequence of actions to go back to simulation time zero. The sequence of actions is defined in the standard draft section 7. The sequence of events gives the possibility for a foreign model to clean up its allocated memory and reinitialize its data structures for example in the callback function for reason *vhpiCbStartOfReset*). The design is not re-elaborated.

Example:

```
void user_app()
{
    /* Application traverse hierarchy */
    ...
    /* Application collect information */
    ...
    vhpi_control(vhpiFinish);
}
```

$$\frac{1}{2} \}$$

11.5 vhpi_create()

vhpi_create()			
Synopsis:	Create a vhpiProcessStmtK or a vhpiDriverK for a vhpi foreign model or a vhpiDriverCollectionK or a vhpiAnyCollectionK		
Syntax:	vhpi_create(kind, refHdl, processHdl)		
Type		Description	
Returns:	vhpiHandleT	A vhpiDriverK or vhpiProcessStmtK or vhpiDriverCollection handle on success, null on failure.	
Type		Name	Description
Arguments:	vhpiClassKindT	kind	Class kind of the handle to be created
	vhpiHandleT	refHdl	Handle to a basic signal or to a foreign architecture
	vhpiHandleT	processHdl	Handle to a vhpiProcessStmtK or null
Related functions:			

vhpi_create () shall be used to create a vhpiDriverK of a VHDL basic signal to drive a VHDL signal from a VHPI foreign model, or to create a vhpiProcessStmtK within a vhpi foreign model, or to create a collection of drivers. This function should only be called during elaboration of a foreign model for creating drivers and processes. There is no restriction on when creation of collections can occur. The first argument, *kind*, specifies the kind of handle to be created (*vhpiDriverK*, *vhpiProcessStmtK* or *vhpiDriverCollectionK*). If *kind* is set to *vhpiDriverK*, the function creates and returns a driver for the basic signal/process pair respectively denoted by the handles *refHdl* and *processHdl*. If *kind* is set to *vhpiProcessK*, the function creates and returns a vhpiProcessStmtK for the foreign architecture denoted by the handle *refHdl*, the last parameter is set to null. For creation of collections, the reference handle must be null for the first time the collection handle is created or must be the collection handle for the subsequent calls when a driver handle is appended to the collection. The third parameter handle can either be a driver handle or a collection handle. The function returns a handle of the requested kind on success and null on failure.

Note: Interleaving addition of elements to the collection while iterating over the members has unspecified behaviour.

Example:

```

void create_vhpi_driver(archHdl)
vhpiHandleT archHdl; /* handle to a foreign architecture */
{
    vhpiHandleT drivHdl, sigItr, sigHdl, processHdl;
    vhpiHandleT arr_driv[MAX_DRIVERS];
    int i = 0;

    if (!vhpi_get(vhpiIsForeignP, archHdl))
        return;
    /* create a VHPI process */
    processHdl = vhpi_create(vhpiProcessK, archHdl, NULL);
    /* iterate on the signals declared in the architecture and create a
       VHPI driver and process for each of them */
    sigItr = vhpi_iterator(vhpiSigDecls, archHdl);
    if (!sigItr) return;
    while (sigHdl = vhpi_scan(sigItr)) {
        drivHdl = vhpi_create(vhpiDriverK, sigHdl, processHdl);
        arr_driv[i] = drivHdl;
        i++;
    }
}

```

```

1  }
2  Issue I 20: Francoise fix example below
3
4  void create_vhpi_collection(sigHdl)
5  vhpiHandleT sigHdl; /* handle to a signal */
6  {
7  vhpiHandleT itBasic, basicH, itDriver, driverH;
8  vhpiHandleT h = NULL;
9
10     itBasic = vhpi_iterate(vhpiBasicSignals, sigHdl);
11     while (basicH = vhpi_scan(itBasic)) {
12         itDriver = vhpi_iterator(vhpiDrivers, basicH)
13         while (driverH = vhpi_scan(itDriver)) {
14
15             h = vhpi_create( (vhpiDriverCollectionK, h, driverH);
16         }
17     }
18 }
19
20

```

11.6 *vhpi_disable_cb()*

vhpi_disable_cb()			
Synopsis:	Disable a callback that was registered using vhpi_register_cb().		
Syntax:	vhpi_disable_cb(cbHdl)		
Type		Description	
Returns:	int	0 on success, 1 on failure.	
Type		Name	Description
Arguments:	vhpiHandleT	cbHdl	A callback handle of kind vhpiCallbackK
Related functions:	Use vhpi_enable_cb() to re-enable the callback		

vhpi_disable_cb () shall be used to disable a callback that was registered using *vhpi_register_cb()*. The argument to this function should be a handle to the callback. The function returns 0 on success and 1 on failure.

11.7 *vhpi_enable_cb()*

vhpi_enable_cb()			
Synopsis:	Enable a callback that was registered using <code>vhpi_register_cb()</code> .		
Syntax:	<code>vhpi_enable_cb(cbHdl)</code>		
Type		Description	
Returns:	int	0 on success, 1 on failure.	
Type		Name	Description
Arguments:	vhpiHandleT	cbHdl	A callback handle of kind <code>vhpiCallbackK</code>
Related functions:	Use <code>vhpi_disable_cb()</code> to disable a callback		

vhpi_enable_cb () shall be used to re-enable a callback that was disabled. The callback was disabled at the registration with the flags set to *vhpiDisable* or was disabled by a call to *vhpi_disable_cb ()*. The argument to this function should be a handle to the callback. The function returns 0 on success and 1 on failure.

Example:

```

void find_cbks()
{
    vhpiHandleT cbHdl, cbItr;
    vhpiStateT cbState;

    /* iterate on the registered callbacks and re-enabled the disabled ones
    */
    cbItr = vhpi_iterator(vhpiCallbacks, objHdl);
    if (!cbItr) return;
    while (cbHdl = vhpi_scan(cbItr)) {
        cbState = vhpi_get(vhpiStateP, cbHdl);
        if (cbState == vhpiDisable)
            vhpi_enable_cb(cbHdl);
    }
}

```

11.8 vhpi_format_value

vhpi_format_value()			
Synopsis:	Format a value into another format representation		
Syntax:	vhpi_format_value(valueInP, valueOutp)		
Type		Description	
Returns:	int	0 on success, non 0 on failure	
Type		Name	Description
Arguments:	const vhpiValueT *	valuep	Pointer to the input value
	vhpiValueT *	valuep	Pointer to the output value
Related functions:	Use vhpi_get_value to get an object value Use vhpi_get_time() to get the current simulation time		

vhpi_format_value() shall change the representation of a value to a requested format. This function takes two value pointers, the first one is the original value, the second one is the output value. The first value contains the value in a given format, the second value structure should have:

- the format field set to the requested format,
- the bufSize field set to size of the user allocated buffer (if formatting values of array type),
- the unit field set to the physical unit position for time or physical type unit conversions if formatting time or physical values,
- the union field which corresponds to the requested format set to point the user allocated value.

Both input and output value and value buffers shall be allocated by the caller. This function shall be used to format value into non native format representations or to do unit conversions for time or physical types. The input value may have been obtained by `vhpi_get_value`, or be a value returned by a callback on value change.

The interface does not define the legal format conversions.

The function returns 0 on success and non zero on failure to get the value. In case the buffer size of the output value (`valuep->bufSize`) allocated by the user is insufficient, `vhpi_format_value` returns a positive value which indicates the required buffer size in bytes for the converted value. If a negative value is returned, an error occurred and can be checked immediately after the **vhpi_format_value()** call by calling **vhpi_check_error()**. An error is generated if the size of the buffer is not sufficient.

The following errors are possible:

- Either of the value pointers is NULL.
- *Bad format specified*: the given format is inappropriate for the format of the input value, or has not been set. For example, if the input format is `vhpiCharVal`, the requested format cannot be `vhpiRealVal`.
- *Overflow*: the value does not fit, for example requesting the value of a real as an integer may result in an overflow. The value is returned but truncated.

The value structure (see table in `vhpi_get_value`) must have been allocated by the user. The **format** field must have been set by the user. The space to hold the value should be allocated by the user and the **bufSize** field to the size of the allocated buffer..

1 On the successful operation, the corresponding union field of the output value will be set by
2 **vhpi_format_value**.

3
4 For time or physical values the unit field must be set to the physical position of the unit of representation of
5 the value (1 being the base unit for physical types).

6
7
8 Example:

```
9  /* converting a real value to an integer value */
10 struct vhpiValueS value, newValue;
11 vhpiValueT *valuep, *newValuep;
12 struct vhpiErrInfoS errInfo;
13
14 valuep = &value;
15 newValuep = &newValue;
16 value.format = vhpiRealVal;
17
18 if (vhpi_get_value(objHdl, valuep))
19     vhpi_check_error(&errInfo);
20 newValue.format = vhpiIntVal;
21 if (vhpi_format_value(valuep, newValuep))
22     vhpi_check_error(&errInfo);
23
24 /* converting a time value from vhpiFs unit(precision of the simulator)
25 to vhpiNs unit */
26
27 value.format = vhpiTimeVal;
28 vhpi_get_value(objHdl, valuep);
29
30 newValue.unit = 1000000; /* physical position of ns */
31 newValue.format = vhpiTimeVal;
32 if (vhpi_format_value(valuep, newValuep))
33     vhpi_check_error(&errInfo);
34
35
```

11.9 vhpi_get()

vhpi_get()			
Synopsis:	Get the value of an integer based property of an object		
Syntax:	vhpi_get(prop, hdl)		
Type		Description	
Returns:	vhpiIntT	Value of the property	
Type		Name	Description
Arguments:	vhpiIntPropertyT	prop	An enumerated integer property constant representing the property of an object for which to obtain the value
	vhpiHandleT	hdl	Handle to an object
Related functions:	Use vhpi_get_str() to get string valued properties. Use vhpi_get_real to get real valued properties.		

vhpi_get() shall return the value of an object property of type `vhpiIntPropertyT`. For properties that are boolean properties (have 2 possible values **1** for **true** and **0** for **false**). Some properties such as **vhpiSizeP** may return any integer, while some other properties return a defined value; for such properties (example **vhpiModeP**), the VHPI header file predefines the integer value to be returned.

11.10 vhpi_get_cb_info()

vhpi_get_cb_info()			
Synopsis:	Retrieve information about a callback registered with vhpi_register_cb()		
Syntax:	vhpi_get_cb_info(hdl, cbDatap)		
	Type	Description	
Returns:	PLI_INT32	0 on success, 1 on failure	
	Type	Name	Description
Arguments:	vhpiHandleT	hdl	Handle to the callback
	vhpiCbDataT	cbDatap	Pointer to a structure containing callback information.
Related functions:	Use vhpi_register_cb() to register a callback.		

vhpi_get_cb_info() shall be used to retrieve callback information for a registered callback. The information is returned in a data structure that shall be allocated by the caller. The caller only allocates the vhpiCbDataS structure.

The cbDatap argument should point to a vhpiCbDataT structure defined by the VHPI standard header file. The data structure fields are described in section 8.2.1 describing **vhpi_register_cb()**. The cbData argument memory must be allocated by the caller. The first argument should be a handle to the callback of kind vhpiCallbackK. The callback information returned is equivalent to the callback data information that was passed at the registration of the callback. If the callback was a time callback and therefore time information was supplied, vhpi_get_cb_info must convey back this information by setting the time field of the vhpiCbDataS structure to point to a time structure allocated by the VHPI interface which contains similar information to the registration call.

```
typedef struct vhpiCbDataS {
    int reason;          /* the reason of the callback */
    (void) (*cbf) (const struct vhpiCbDataS *); /* the callback
                                                function
                                                pointer */
    vhpiHandleT obj;     /* a handle to an object */
    vhpiTimeT *time;     /* a time */
    vhpiValueT *value;   /* a value */

    void *user_data;     /* user data information */
} vhpiCbDataT, *vhpiCbDatap;
```

11.11 vhpi_get_data()

vhpi_get_data()			
Synopsis:	Retrieve data from a saved location.		
Syntax:	vhpi_get_data(int id, void *dataLoc, int numBytes)		
	Type	Description	
Returns:	PLI_INT32	the number of bytes read, 0 on error	
	Type	Name	Description
Arguments:	PLI_INT32	id	an identifier denoting a position in a saved location
	PLI_VOID *	dataLoc	the address in which to put the data read
	PLI_INT32	numBytes	the requested number of bytes to read
Related functions:	Use vhpi_put_data to store data in a saved location		

vhpi_get_data() shall be used to retrieve “numBytes” of data for a given “id” from a saved file. The data is placed at the address pointed to by “dataLoc”. The memory pointed to by dataLoc must have been properly allocated by the caller. The first call for a given “id” will retrieve “numBytes” of data starting at was placed into the save location with the first call to **vhpi_put_data()** for the same “id”. The returned value is the number of bytes that were read. The user is responsible to check if the number of bytes read in is equal to the number of bytes requested. Each subsequent call with the same id will start retrieving data where the last call left off.

It is acceptable for an application to read in less bytes than what was stored for a given id with **vhpi_put_data()**, a warning should be issued. In this case, the dataLoc address is filled up with the data left for the given id and the remaining bytes will be filled up with ‘\0’. The return value shall be the actual number of bytes retrieved.

vhpi_get_data() can only be called from a callback routine which was registered for reason *vhpiCbStartOfRestart* or *vhpiCbEndOfRestart*. Such callbacks must have been registered during the *vhpiCbStartOfSave* or *vhpiCbEndOfSave* execution. The reason is that the restart callback information (in particular the ids) must be saved in the simulation save location. A good way to record the id of an application is to pass it in the *user_data* field of the callback data of reason *vhpiCbStartOfRestart* or *vhpiCbEndOfRestart*. The size of the *user_data* field is a pointer to char which is enough to contain an int.

Example: A consumer routine which retrieves stored data from a save location.

See also the example in **vhpi_put_data()** for how this restart callback was registered.

```
/* type definitions for private data structures to save used by the
foreign models or applications */
struct myStruct{
    struct myStruct *next;
    int d1;
    int d2;
}
void consumer_restart(vhpiCbDataT *cbDatap)
{
    int status;
    int cnt = 0;
    struct myStruct *wrk;
    int dataSize = 0;
```

```

1  /* get the id for this restart callback */
2  int id = (int) cbData->user_data;
3  /* get the number of structures */
4  status = vhpi_get_data(id, (char *)&cnt, sizeof(int));
5  if (status != sizeof(int))
6      vhpi_assert(vhpiError, "Data read is not an int %d\n", status);
7  /* allocate memory to receive the data that is read in */
8  firstWrk = calloc(cnt, sizeof(struct myStruct));
9
10 /* retrieve the data for the first structure */
11 dataSize = cnt * sizeof(struct myStruct);
12 status = vhpi_get_data(id, (char *)wrk, dataSize);
13 if (status != dataSize)
14     vhpi_assert(vhpiError, " cannot read %d data structures\n", cnt );
15
16 /* fix up the next pointers in the link list:
17    recreate the linked list */
18 for (wrk = firstWrk; cnt >0; cnt--)
19 {
20     wrk->next = wrk++;
21     wrk = wrk->next;
22 }
23 } /* end of consumer_restart */

```

11.12 vhpi_get_foreignf_info()

vhpi_get_foreignf_info()			
Synopsis:	Retrieve information about a foreign model or application functions		
Syntax:	vhpi_get_foreignf_info(hdl, foreignDatap)		
Type		Description	
Returns:	PLI_INT32	0 on success, 1 on failure	
Type		Name	Description
Arguments:	vhpiHandleT	hdl	Handle to the foreign architecture, procedure, function or application
	vhpiForeignDataT	foreignDatap	Pointer to a structure containing model information.
Related functions:	Use vhpi_register_foreignf() to register foreign model and application elaboration and execution functions. Use the iteration function vhpiForeignfs to get the foreign models and applications registered in a tool session. Use vhpi_get_cb_info() to retrieve information about a registered callback.		

vhpi_get_foreignf_info() shall be used to retrieve foreign function information for foreign models and applications. The information is returned in a data structure that shall be allocated by the caller. On the return, the foreignDatap data structure is populated with the function pointers of the foreign model if bound, the kind of foreign model (vhpiArchF, vhpiProcF, vhpiFuncF, or vhpiAppF) and the library and model string names. The populated information is read only and the lifetime of the strings is unspecified. The foreignDatap argument should point to a vhpiForeignDataT structure defined by the VHPI standard header file. The data structure fields are described in section 11.28 **vhpi_register_foreignf()**. The foreignData argument memory must be allocated by the caller. The first argument should be a handle to a foreign model. The handle kind is vhpiForeignFK (refer to the foreign model class diagram). **vhpi_get_foreignf_info()** does not force any function binding; it shall return the function pointers if the model has been bound to its C behaviour or null if not bound yet. A warning should be issued that the foreign model has not been bound yet.

```
typedef struct vhpiForeignDataS {
    vhpiForeignT kind; /* the foreign model class kind:
                        vhpi[ArchF,ProcF,FuncF, AppF]K */
    char *libraryName; /* the library name that appears in the
                        VHDL foreign attribute string */
    char *modelName; /* the model name that appears in the
                       VHDL foreign attribute string PA28*/
    void (*elabf)( const vhpiCbDataT *);
                    /* the callback function pointer for
                       elaboration of foreign architecture */
    void (*execf)( const vhpiCbDataT *);
                    /* the callback function pointer for
                       initialization/simulation execution of
                       foreign architecture, procedure,
                       function or application */
}
```

```
} vhpiForeignDataT, *vhpiForeignDatap;
```

1

11.13 vhpi_get_next_time()

vhpi_get_next_time()			
Synopsis:	Retrieve the next simulation time when some activity is scheduled		
Syntax:	vhpi_get_next_time(time_p)		
Type		Description	
Returns:	int	0 on success, vhpiNoActivity if nothing is scheduled, non zero on other errors	
Type		Name	Description
Arguments:	vhpiTimeT *	time_p	A pointer to a time structure containing the next time information
Related functions:	Use vhpi_get_phys(vhpiPrecisionP, NULL) to get the TIME value precision. Use vhpi_get_phys(vhpiTimeUnitP, NULL) to get the simulator time unit. Use vhpi_get_time() to get the current simulation time.		

vhpi_get_next_time() shall return the next active time if this function is called during postponed process or end of time phase and the current time when called in any other phase. The function returns 0 when there is a next scheduled time, and the time argument provides the absolute time value for the next event. If no event is scheduled, the time low and high fields should be both set to represent the value of Time'HIGH and the function should return vhpiNoActivity (defined to be the constant 1). If there is any error during the execution of this function, the function returns a non zero value (other than vhpiNoActivity), the time value is unspecified. This function can be called at the end of time step or at end of initialization.

Example:

```

vhpiTimeT time;

switch (vhpi_get_next_time(&time))
{
    case vhpiNoActivity:
        vhpi_printf("simulation is over, %d %d\n", time.high, time.low);
        break;
    case 0:
        vhpi_printf("time = %d %d\n", time.high, time.low);
        break;
    default:
        vhpi_check_error(&errInfo);
        break;
}

```

11.14 vhpi_get_phys()

vhpi_get_phys()	
Synopsis:	Get the value of a physical property of an object
Syntax:	vhpi_get_phys(prop, hdl)

Type		Description	
Returns:	vhpiPhysT	Value of a physical property	
Type		Name	Description
Arguments:	vhpiPhysPropertyT	prop	An enumerated physical property constant representing the property of an object for which to obtain the value
	vhpiHandleT	hdl	Handle to an object
Related functions:	Use vhpi_get() to get integer valued properties. Use vhpi_get_str to get string valued properties.		

vhpi_get_phys() shall return the value of an object property of type vhpiPhysPropertyT. The value is returned as a vhpiPhysT. The returned value is unspecified in case of an error.

Example:

```
vhpiHandleT type; /* a physical type declaration */;
vhpiHandleT range = vhpi_handle(vhpiConstraint, type);
vhpiPhysT phys = {0,0};

phys = vhpi_get_phys(vhpiPhysRightBoundP, range);
vhpi_printf(" right bound of physical type is %d %d \n", phys.low,
phys.high);
```

11.15 vhpi_get_real()

vhpi_get_real()			
Synopsis:	Get the value of a real property of an object		
Syntax:	vhpi_get_real(prop, hdl)		
Type		Description	
Returns:	vhpiRealT	Value of a real property	
Type		Name	Description
Arguments:	vhpiRealPropertyT	prop	An enumerated real property constant representing the property of an object for which to obtain the value
	vhpiHandleT	hdl	Handle to an object
Related functions:	Use vhpi_get() to get integer valued properties. Use vhpi_get_str to get string valued properties.		

vhpi_get_real() shall return the value of an object property of type vhpiRealPropertyT. The value is returned as a vhpiRealT. The return value is unspecified in case of an error.

Example:

```
1  vhpiHandleT type; /* a float type declaration */;
2  vhpiHandleT range = vhpi_handle(vhpiConstraint, type);
3
4  vhpi_printf(" right bound of floating type is %f\n",
5  vhpi_get_real(vhpiFloatRightBoundP, range));
6
7
```

11.16 *vhpi_get_str()*

vhpi_get_str()			
Synopsis:	Get the value of a string property of an object		
Syntax:	vhpi_get_str(prop, hdl)		
Type		Description	
Returns:	const PLI_BYTE8 *	Pointer to a character string that represents the property value	
Type		Name	Description
Arguments:	vhpiStrPropertyT	prop	An enumerated string property constant representing the property of an object for which to obtain the value
	vhpiHandleT	hdl	Handle to an object
Related functions:	Use <code>vhpi_get()</code> to get integer valued properties. Use <code>vhpi_get_real</code> to get real valued properties.		

vhpi_get_str() shall return the value of an object property of type `vhpiStrPropertyT`. The next call to `vhpi_get_str()` may override the previous string value returned by the prior `vhpi_get_str()` call, therefore if the string is to be used after this call, the string should be copied by the user to another location. The function returns `NULL` on error.

Example:

```

char name[MAX_LENGTH];
vhpiHandleT inst = vhpi_handle_by_name(":ul", NULL);

strcpy(name, vhpi_get_str(vhpiDefNameP, inst));
vhpi_printf("instance ul is a %s\n", name);

```

11.17 vhpi_get_time()

vhpi_get_time()			
Synopsis:	Retrieve the current simulation time		
Syntax:	vhpi_get_time(time_p, cycles_p)		
Type		Description	
Returns:	void		
Type		Name	Description
Arguments:	vhpiTimeT *	time_p	A pointer to a time structure containing time information
	long *	cycles_p	The number of relative or absolute delta cycles.
Related functions:	Use vhpi_get_phys(vhpiPrecisionP, NULL) to get the simulator precision. Use vhpi_get_phys(vhpiSimTimeUnitP, NULL) to get the simulator time unit.		

vhpi_get_time() shall return the current simulation time. The time value is returned using in the format specified in the time structure. The caller must allocate the time structure. The time is returned in the base unit of type time. In order to get the time in an different unit or format the `vhpi_format_value()` function shall be used.

If `time_p` is not NULL and `cycles_p` is not NULL, the `time_p` argument is set to the current simulation time `Tc`, the `cycles_p` argument is set to the current number of delta cycles from the beginning of that time step . A delta cycle is counted even if not completed. If the `time_p` argument is NULL, the `cycles_p` argument is set to the the absolute number of simulation cycles executed from the beginning of simulation. `Cycles_p` should be a pointer to long. The time is the current time, and the current number of delta cycles even if the time step or current delta is not completed yet.

```
typedef struct vhpiTimeS {
    vhpiInt high;
    vhpiInt low;

} vhpiTimeT;
```

Issue Francoise: `vhpiTimeS` structure differs from header files.

Example:

```
vhpiTimeT time;

vhpi_get_time(&time, NULL);
vhpi_printf("time = %d %d\n", time.high, time.low);
```

11.18 vhpi_get_value()

vhpi_get_value()			
Synopsis:	Get the value of an object or name, driver or transaction		
Syntax:	vhpi_get_value(objHdl, valuep)		
Type		Description	
Returns:	PLI_INT32	0 on success, non 0 on failure to get the value	
Type		Name	Description
Arguments:	vhpiHandleT	objHdl	Handle to an object which has a value
	vhpiValueT *	valuep	Pointer to a value
Related functions:	Use vhpi_put_value() to set an object to a value. Use vhpi_schedule_transaction to update the waveform of a signal driver.		

vhpi_get_value() shall get the value of an object or expression which possess a value. Classes of objects which have a value have the **vhpi_get_value** operation (see class diagrams). The function takes 2 arguments: *objHdl*, handle to the object to get the value from, *valuep*, pointer to a value structure that contains information on how to format the value. The function returns 0 on success and non zero on failure to get the value. In case the buffer size of the value (in valuep->bufSize) allocated by the user is insufficient, vhpi_get_value returns a positive value which indicates the required buffer size in bytes for the value. If a negative value is returned, an error occurred and can be checked immediately after the **vhpi_get_value()** call by calling **vhpi_check_error()**. Also an error if a buffer is provided and the size of the buffer is not sufficient.

The following errors are possible:

- This is *not a valid object* to get a value from: the object does not carry a value or the object handle is NULL.
- *Bad format specified*: the given format is inappropriate for the subtype of the object, or has not been set.
- *Overflow*: the value does not fit, for example requesting the value of a real as an integer may result in an overflow. The value is returned but truncated.
- *Value is unavailable*: the simulator has made some performance optimizations that makes this object and value inaccessible.

The value structure (see table 4) must have been allocated by the user. The format field must have been set by the user. The space to hold the value should be allocated by the user and the bufSize field to the size of the allocated buffer..

On the successful operation, the corresponding union value field will be set by vhpi_get_value (see table 4).

Values of objects of physical type are returned in base units with the *unit* field set to 1. Values of physical literals are returned in the units of the literal.

In case where the format is set by the user to *vhpiObjTypeVal*, the returned value will be returned in the most appropriate format for the type of the object. On the return, the interface will set the format field. Table 5 specifies which format will be chosen for each VHDL basic type.

vhpi_get_value() can retrieve the value of VHDL scalar types, value of access types, and arrays of scalars. In order to get values of complex types which do not fall in these categories, VHPI provides methods to:

- iterate on the sub-element fields of an object of a record type with the method *vhpiSelectedNames*.
- iterate on the sub-element index of an object of an array type with the method *vhpiIndexedNames*.
- access the dereferenced object from a variable object of an access type with the one-to-one method *vhpiDerefObj*.

Given a reference handle of the object of a composite type, it is possible to iterate through each record field or array element and for each handle of the iterator, call *vhpi_get_value()* to get the value of that sub-element. The iteration methods are respectively *vhpiSelectedNames*, and *vhpiIndexedNames*.

```
vhpi_iterate(vhpiSelectedNames, compObjHdl)
```

```
vhpi_iterate(vhpiIndexedNames, compObjHdl)
```

These methods return an ordered list of elements.

In case of values of multi-dimensional arrays, each returned handle represents an element in that array. If the array has 3 dimensions r, c, t, each handle returned can be represented by the 3 indices in r_idx, c_idx and t_idx. The elements are returned by varying the index of the last index constraint first. For each index range, the variation starts by the left index to the right index, independently of the direction of the range.

Example:

```
type array (1 to 2), (4 to 6), (8 downto 7) of integers;
```

iterating on the array elements will return the elements represented by the following:

```
(1,4,8) (1,4,7) (1,5,8) (1,5,7) (1,6,8) (1,6,7)
(2,4,8) (2,4,7) (2,5,8) (2,5,7) (2,6,8) (2,6,7)
```

In the case of arrays of arrays, each returned handle represents an element in the base array.

Example:

```
type arr_of_arr (1 to 2) of bit_vector(1 to 16);
```

```
signal s: arr_of_arr;
```

```
vhpi_iterate(vhpiIndexedNames, sHdl); // sHdl is a handle to signal s;
```

The iteration function will return handles to s(1) and s(2) which are vectors of 16 bits each. The kind of these handles is *vhpiIndexedNameK*. The value of each handle will be the value of the 16 bit vector it refers to.

In the case of an object of a record type, iterating through the record fields should return the selected object fields in the order they are declared. The kind of these handles is *vhpiSelectedNameK*. The value of such a handle will be the value of the selected field of the object. The *vhpiSelectedNames* iteration method can only be called on an object which type is a record type. The *vhpiIndexedNames* iteration method can only be called on an object which type is an array type.

The reference handle kinds passed to the *vhpiSelectedNames* and *vhpiIndexedNames* iteration methods can either be members of the *objDecl* class or of the *name* class.

These 2 methods allow to walk through any complex composite VHDL object.

The 1-to-1 method *vhpiDerefObj* allows to access the dereference allocated object which is designated by the access value of the variable. The reference handle must denote a *vhpiVarDeclK* kind of handle or a sub-element of a variable which is of an access type. The handle returned by this method is of kind *vhpiDerefObjK*. This class is a sub-class of the class name and inherits the properties and methods of the class name. In particular, the *vhpiNameP* property, *vhpiSizeP* (size in scalars of the dereferenced object), the *vhpi_get_value()* operation. A dereference object has no simple name according to the LRM page 45, therefore the *vhpiNameP* should return NULL and an error should be generated (Issue I002). The dereference object has a subtype which is the subtype of the accessed value. As a consequence, from a derefObject which is of a composite, the iteration methods *vhpiIndexedNames* and *vhpiSelectedNames* may be allowed as well as the *vhpiDerefObj* method if the access value is again of an access type. In the same way, from an *vhpiIndexedNameK* or *vhpiSelectedNameK*, if the object designated is of an access type, the *vhpiDerefObj* method is allowed.

Handle kinds that have a value are:

1. all sub-classes of the objDecl class: *vhpiConstDeclK*, *vhpiSigDeclK*, *vhpiFileDeclK*, *vhpiVarDeclK*, *vhpiGenericDeclK*, *vhpiPortDeclK*, *vhpiSigParamDeclK*, *vhpiVarParamDeclK*, *vhpiConstParamDeclK*, *vhpiFileParamDeclK*

Their value can be fetched if the object declaration has been elaborated. If the value is fetched at the end of elaboration, the value is the default ('left) or initial value of the object provided in the declaration. The value of a generic after elaboration will be the value after generic propagation. During simulation, the value fetched is the value of the object at this particular time.

For a *vhpiFileDeclK*, the value is the logical name of the file. The value is of type string. The value is the string value supplied in the declaration if present or the logical name the file was associated with during a call to FILE_OPEN if the file was opened during simulation. If the file is not opened at the time of the query the value *str* field is set to NULL and an error is generated.

For a variable of an access type, the access value can be fetched with the format *vhpiPtrVal*: the access value is the address of the allocated object. The dereference value designated by the current access value of the variable can be fetched from a handle of the dereference object (*vhpiDerefObjK*) which is obtained after applying the *vhpiDerefObj* method to the variable handle. If the variable has an access value of 0 (null) it does not designate an allocated object. In that case it is an error to apply the *vhpiDerefObj* method (Dereferencing a null pointer); the *vhpiDerefObj* method should return a null handle and an error should be generated.

The access value designates the created object (just like a pointer). This is different from the value of the object which can be fetched by dereferencing the object. The value of a dereference name (xyz.ALL) will be the dereference value pointed by the object xyz. The handle kind of a dereference name is *vhpiDerefObjK*. The default value of a variable of an access type is NULL (NULL pointer). The initial access value of a variable with an initial expression will be the access value of the initial expression.

A dereference object (*vhpiDerefObjK*) has a value which can be obtained with *vhpi_get_value* and the format field set to a format applicable to the basic type corresponding to the dereference value. For example, for a dereference value of a variable of access to integer, the format should be set to *vhpiIntVal*, and the handle denoting the dereference object.

For foreign subprogram calls, it is possible to get the actual values associated with the formal parameters. Subprograms are dynamically elaborated therefore the values of their parameters or declared items can only be fetched when the program is currently executing or is suspended.

We provide a method to get the current equivalent process and a method to access the stack of an equivalent process (see subprogram call class diagram). The user can only fetch the values of parameters or declared items if the subprogram call is either the current executing process or is on the call stack of the current executing process or is a suspended process or on the stack of a suspended process.

Subprogram parameter values can only be fetched when the subprogram is executed because they come to existence dynamically. In order to get a value for either a parameter or a declared item within that subprogram, the static as well as dynamic info must be provided (stack frame level).

2. any sub-class of the class name has a value (*vhpiIndexedNameK*, *vhpiSliceNameK*, *vhpiSelectedNameK*, *vhpiAttrNameK*).

There is the possibility of getting a value for handles of any of the sub-classes of class literal using *vhpi_get_value*. Another approach is to use the properties defined for each of the literal sub-classes, which do not require allocation of a value buffer. We defined different properties for each sub-classes: *vhpiIntValP* for class *vhpiIntLiteralK*, *vhpiRealValP* for class *vhpiRealLiteralK*, and *vhpiStrValP* for classes *vhpiStringLiteralK*, *vhpiBitStringLiteralK*, *vhpiCharLiteralK* and *vhpiEnumLiteralK*.

It is not possible to fetch directly the value of any other expression such as an aggregate, typeConv or function call for example.

3. Simulation objects:

A driver (vhpiDriverK) has a value which is its current driving value. This driving value can only be fetched after simulation initialization phase has been completed.

The value of a transaction object handle (vhpiTransactionK) can also be fetched during a simulation session.

Values can be fetched after simulation initialization has completed in a simulation session, or after elaboration in an elaboration session. (Francoise: Does this apply to simulation objects? Or to all objects which have a value?)

These class kinds have an operation vhpi_get_value() in the object class diagram.

Examples: The following function get_object_value() shows how to obtain value of array type, record and scalar types. As written, the function is able to get the value of the signals "bit3" and "rec1". The default cases of the switch statements need to be completed to be able to get values of objects of any type.

```
type bit3 is array (1 to 3) of std_logic;

type myrecord is record
  i: integer;
  r: real;
  b3: bit3;
end record;

-- array of records: my_reccarray
type my_reccarray is array (0 to 2) of myrecord;
-- multi-dimension: array 2 dimensions of time values
type my_2dim is array (0 to 2, 1 to 3) of time;

type word is array of (1 to 8) of bits;
-- array of array
type mem is array (1 to 4) of word;

signal bits : bit3 := (std0, std1, stdu);
signal rec1 : myrecord := (34, 2.0, (STD0, STD0, STD0));
signal rec2 : my_reccarray := ((34, 2.0, (others => STD0)), (35, 3.0,
(others => STD1)));
signal arr2dim : my_2dim := ((0 ns, 1 ns, 2 ns), (3 ns, 4 ns, 5 ns), (6
ns, 7 ns, 8 ns));
signal arroffarr : mem := ("0000_0000", "0000_0001", "0000_0010",
"0000_0011");

void get_object_value(vhpiHandleT sigHdl)
{
  vhpiHandleT elemHdl, baseHdl;
  struct vhpiValueS value;
  vhpiValueT * valuep = &value;
  int size;
  char *buffer = NULL;

  /* access the value of signal sigHdl*/

  value.bufSize = 0
  value->value = NULL;
  size = vhpi_get_value(sigHdl, valuep);
```

```

1  if (size > value.bufSize) {
2      buffer = malloc (sizeof(size));
3      value.bufSize = size;
4  }
5
6  baseHdl = vhpi_handle(sigHdl, vhpiBaseType);
7  switch (vhpi_get(vhpiKindP, baseHdl)) {
8  case vhpiArrayTypeDeclK:
9      {
10         elemHdl = vhpi_handle(vhpiElemType, baseHdl);
11         switch (vhpi_get(vhpiKindP, elemHdl))
12         {
13             case vhpiIntTypeDeclK:
14                 value.format = vhpiIntVecVal;
15                 value.intgs = buffer;
16                 vhpi_get_value(sigHdl, &value);
17                 for (value.elemScalars, value.intgs; value.elemScalars=0;
18                     value.elemScalars--, (value.intgs)++)
19                     vhpi_printf("%s [ %d] = %d \n",
20                                 vhpi_get_str(sigHdl, vhpiName),
21                                 value.elemScalars, value.intgs);
22                 break;
23             case vhpiEnumTypeDeclK:
24                 if (!strcmp(vhpi_get_str(vhpiCaseNameP, elemHdl) == "CHARACTER"))
25                 {
26
27                     value.format = vhpiStrVal;
28                     value.str = buffer;
29                     vhpi_get_value(sigHdl, &value);
30                     vhpi_printf("%s = %s\n", vhpi_get_str(vhpiName, SigHdl),
31 value.str);
32                 }
33                 else {
34                     value.format = vhpiEnumVecVal;
35                     value.enumvs = buffer;
36                     vhpi_get_value(sigHdl, &value);
37                     for (value.elemScalars, value.enumvs; value.elemScalars=0;
38                         value.elemScalars--, (value.enumvs)++)
39                         vhpi_printf("%s [ %d] = %d \n",
40                                     vhpi_get_str(sigHdl, vhpiName),
41                                     value.elemScalars, value.enumvs);
42                 }
43                 break;
44             case vhpiPhysTypeDeclK:
45
46                 if (!strcmp(vhpi_get_str(vhpiCaseNameP, elemHdl) == "TIME"))
47                 {
48                     value.format = vhpiTimeVecVal;
49                     value.times = buffer;
50                     vhpi_get_value(sigHdl, &value);
51
52                     for (value.elemScalars, value.times; value.elemScalars=0;
53                         value.elemScalars--, (value.times)++)
54                         vhpi_printf("%s [ %d] = %d %d\n",
55                                     vhpi_get_str(sigHdl, vhpiName),

Table 5: vhpiObjTypeVal returned formats

11.19 *vhpi_handle()*

vhpi_handle()			
Synopsis:	Return the destination handle of a one-to-one relationship		
Syntax:	vhpi_handle(oneRel, refHdl)		
	Type	Description	
Returns:	vhpiHandleT	returns the target handle or NULL.	
	Type	Name	Description
Arguments:	vhpiOneToOneT	oneRel	An integer constant denoting the one-to-one relationship to traverse
	vhpiHandleT	refHdl	Handle to the reference object of the relationship

vhpi_handle() shall be used to traverse either:

1. a one-to-one unnamed directed relationship that exists between an object denoted by *refHdl* and an object of type *oneRel*.
2. a one-to-one tagged directed relationship that exists between two classes.

If the multiplicity of the association is 0..1, it is possible to not obtain a handle by traversing that relationship and the function *vhpi_handle()* will return NULL.

If the multiplicity of the association is 1, the traversal of the relationship should always return a handle.

Example: The following code shows the traversal of several one-to-one relationships. The relationships are illustrated by the class scope diagram.

```

vhpiHandleT get_instance_info(scopeHdl)
vhpiHandleT scopeHdl; /* a handle to a scope */
{
    vhpiHandleT upScopeHdl, duHdl;

    /* escalate the hierarchy one level */
    /* traverse a tagged relationship */
    upScopeHdl = vhpi_handle(vhpiUpperRegion, scopeHdl);
    if (vhpi_get(vhpiKindP, upScopeHdl) == vhpiCompInstStmtK)
    { /* traverse a unnamed relationship */
        duHdl = vhpi_handle(vhpiDesignUnit, upScopeHdl);
        return(duHdl);
    }
    else return(NULL);
} /* end get_instance_info() */

```

11.20 *vhpi_handle_by_index()*

vhpi_handle_by_index()			
Synopsis:	Get a handle to an object using an index position in a parent object.		
Syntax:	vhpi_handle_by_index(itRel, parentHdl, index)		
	Type	Description	
Returns:	vhpiHandleT	A handle to an object.	
	Type	Name	Description
Arguments:	vhpiOneToManyT	itRel	an ordered iteration relationship tag
	vhpiHandleT	parentHdl	the handle to the object from which to obtain the indexed handle.
	PLI_INT32	index	index position of the object for which to obtain a handle for.
Related functions:	Use <i>vhpi_iterator</i> and <i>vhpi_scan()</i> to get each element of the parent handle		

vhpi_handle_by_index() shall be used to get a handle to an object based on the index number of that object within a parent object. The parent object must bear an ordered iteration relationship to the indexed object (*vhpiIndexedNames*) or an integer property denoting the number of elements in the iteration (called *vhpiNumParamsP* for *vhpiParamDecls* iteration, *vhpiNumGensP* for the *vhpiGenDecls* iteration, *vhpiNumPorts* for the *vhpiPortDecls* iteration for example. Such ordered relationships exist for example between an object of type array and its sub-elements, a subprogram call and its formal parameters, a object of type record and its fields, a variable or a derefobj of an access type to an array or record and its sub-Dereference objects (I0023: do we allow shortcut iterations on indexednames and selected names from a variable of an access type?). The first argument must denote an ordered iteration relationship. These ordered iteration relationships are marked “ordered” on the information model. The ordered iterations can also be traversed with the *vhpi_iterator()* and *vhpi_scan()* functions.

vhpi_handle_by_index(itRel, parentHdl, index) returns the handle that would have been returned by creating an iterator of the relationship denoted by *itRel*, and scanning for *index* + 1 times.

Example 1: (I024: fix example subtype/basetype changes)

```

vhpiHandleT find_indexed_constraint(parentHdl, index)
vhpiHandleT parentHdl; /* a handle to a object */
int index; /* the index position of the object to obtain */

{
    vhpiHandleT subtypeHdl, typeHdl, subHdl;

    subtypeHdl = vhpi_handle(vhpiType, parentHdl);
    typeHdl = vhpi_handle(vhpiBaseType, subtypeHdl);
    if (vhpi_get(vhpiIsCompositeP, typeHdl))
    { /* get the given indexed array element or indexed record field
       of the parent object */
        if (vhpi_get(vhpiKindP, typeHdl) == vhpiArrayTypeDeclK)
            subHdl = vhpi_handle_by_index(vhpiConstraints, parentHdl,
                                           index);
        else if (vhpi_get(vhpiKindP, typeHdl) == vhpiRecordTypeDeclK)
            subHdl = vhpi_handle_by_index(vhpiRecordElems, parentHdl,
                                           index);
    }
}

```

```

1                                     index);
2
3         return subHdl;
4     }
5     else return NULL;
6 }
7
8 Example 2:
9 This example shows how to access a formal parameter by index position from a subprogram call handle.
10 This is useful for accessing values of VHDL formal parameters from a foreign subprogram C function
11 implementation. Formal parameter declarations define an order in the interface parameter list.
12
13 void exec_proc(cbDatap)
14 vhpiCbDataT cbDatap; /* the call-data structure of the C foreign
15                        function implementation of a VHDL
16 subprogram
17                        behavior.*/
18
19 {
20
21     vhpiHandleT subpCallHdl, formall, formalIt;
22     int val = 0;
23     vhpiValueT value;
24
25     value.format = vhpiIntVal;
26     value.value->integer = &val;
27     procCallHdl = cbDatap->obj;
28
29     /* get a handle to the first formal parameter of the
30        subprogram call */
31     formall = vhpi_handle_by_index(vhpiParamDecls, subpCallHdl, 0);
32
33     switch(vhpi_get(vhpiModeP, formall))
34     {
35         case vhpiIN:
36             vhpi_get_value(formall, &value);
37             break;
38         case vhpiOUT:
39             vhpi_put_value(formall, &value);
40             break;
41         default:
42             break;
43     }
44
45 Example 3: (I025: fix example)
46 This example shows how to get a handle to a sub-object of a composite type.
47
48 type myrecord is record
49     I: integer;
50     B: bit;
51     AR: array (2 to 4);
52 end record;
53 type myrecord_ptr is access to myrecord;
54 type mybit_vector_ptr is access to bit_vector;
55
56 variable A: array (2 to 5) of bit := ('1', '0', '1', '0');
57 variable M: array ((2 to 5), (3 to 5)) of integer:= (1, 2, 3, 4,
58                                                    5, 6, 7, 8,
59                                                    9,10,11,12);

```

```

1  variable R: myrecord := (9, '0', B"111");
2  variable R_p: myrecord_ptr;
3  variable BV_p: mybit_vector_ptr;
4
5  /* if Ahdl is an handle to variable A */
6  hdl = vhpi_handle_by_index(vhpiIndexedNames, Ahdl, 0)
7  /* returns a handle to A(2) */
8  /* if Mhdl is an handle to variable M */
9  hdl = vhpi_handle_by_index(vhpiIndexedNames, Mhdl, 0)
10 /* returns a handle to M(2,3) */
11 /* if Rhdl is an handle to variable R */
12 hdl = vhpi_handle_by_index(vhpiSelectedNames, Rhdl, 0)
13 /* returns a handle to R.I */
14 /* if Rhdl is an handle to variable R */
15 subeltHdl = vhpi_handle_by_index(vhpiSelectedNames, Rhdl, 2)
16 /* subeltHdl is a handle to R.AR */
17 hdl = vhpi_handle_by_index(vhpiIndexedNames, subeltHdl, 2)
18 /* hdl is a handle to R.AR(4) */
19 /* if BV_phdl is an handle to variable BV_p */
20 hdl = vhpi_handle_by_index(vhpiIndexedNames, BV_phdl, 0)
21 /* returns a handle to BV_p(0) */
22
23 /* if R_phdl is an handle to variable R_p */
24 hdl = vhpi_handle_by_index(vhpiSelectedNames, R_phdl, 0)
25 /* returns a handle to R_p.I */
26
27
28
29

```

11.21 *vhpi_handle_by_name()*

vhpi_handle_by_name()			
Synopsis:	Returns a handle to the named item if found in the search scope.		
Syntax:	vhpi_handle_by_name(name, refHdl)		
Type		Description	
Returns:	vhpiHandleT	A handle on success, NULL if no objects of the given name exists.	
Type		Name	Description
Arguments:	const PLI_BYTE8 *	name	A character string or a pointer to a string containing the full, partial or simple name of an object.
	vhpiHandleT	refHdl	Handle to a reference search region or scope handle or NULL
Related functions:	Use <i>vhpi_get_str()</i> to get the name (<i>vhpiNameP</i>) or full name (<i>vhpiFullNameP</i>) of an object		

vhpi_handle_by_name() shall return a handle to an object that matches the given name. This function can be only applied to objects having the *vhpiFullNameP* property. Francoise: why not the name property ? Is there any object which has the fullname property but not the name property?. The *name* can be the full hierarchical name or a partial hierarchical name of an elaborated object or uninstantiated object. If *refHdl* is NULL, the *name* shall be searched for from the top level of the hierarchy (*vhpiRootInstK*) or from the packages instantiated in the design (*vhpiPackInstK* handles) or from the library context if the *vhpiFullNameP* denotes a full uninstantiated name (*vhpiFullNameP* is the same as *vhpiDefNameP* in the uninstantiated context). If *refHdl* is not NULL, *name* shall be searched from the declarative instantiated region or uninstantiated scope designated by the *refHdl* handle. The function cannot be applied to handles of anonymous types (do we have handles to anonymous types?). For overloaded subprograms or enumeration literals, the name must include the parameter result profile. In this case the name must follow the following syntax:

```
<subp_name> | <enum_literal> ({param_type, } [:return_type])
```

The return type is only necessary for functions and enumeration literals.

vhpi_handle_by_name() will return null if the name is ambiguous or if it cannot find the object of that name.

Example:

This function finds a signal handle given the simple signal name.

```
vhpiHandleT findsignal(sigName)
```

```
char *sigName; /* the signal name */
{
    vhpiHandleT subitr, hdl, subhdl, sigHdl;
    /* first search the signal in the design hierarchy, starting at the
    root instance level and recursively descending into the sub-instances
    */
    itr = vhpi_handle(vhpiRootInst, NULL);
    if (itr) {
        sigHdl = vhpi_handle_by_name(sigName, hdl);
        if (sigHdl)
```

```

1      return sigHdl;
2      else {
3          subitr = vhpi_iterator(vhpiInternalRegions, hdl);
4          if (subitr)
5              while (subhdl = vhpi_scan(subitr)) {
6                  sigHdl = vhpi_handle_by_name(sigName, subhdl);
7                  if (sigHdl)
8                      return sigHdl;
9              }
10     }
11 }
12 itr = vhpi_iterator(vhpiPackInsts, NULL);
13 if (itr)
14     while (hdl = vhpi_scan(itr)) {
15         sigHdl = vhpi_handle_by_name(sigName, hdl);
16         if (sigHdl)
17             return sigHdl;
18     }
19 return NULL;
20 }

```

11.22 *vhpi_iterator()*

vhpi_iterator()			
Synopsis:	Create an iterator handle to the reference handle which has a one-to-many relationship and initialize it to point to the first element of the iteration		
Syntax:	vhpi_iterator(iterType, refHdl)		
Type		Description	
Returns:	vhpiHandleT	An initialized iterator handle on success, NULL if no objects of type iterType exists.	
Type		Name	Description
Arguments:	vhpiOneToManyT	iterType	An integer constant representing the iteration type
	vhpiHandleT	refHdl	Handle to the reference handle
Related functions:	Use <i>vhpi_scan()</i> to get each element of the iteration		

vhpi_iterator() shall be used to traverse one-to-many relationships which are indicated by arrows with a multiplicity of * or 1..* in the information model. This function creates and initializes an iterator handle, whose type is **vhpi_iteratorK** and which can be used by the *vhpi_scan()* function to scan through each object of type *type* which is in a multiple association with the reference object *refHdl*. If there are no objects of type *type* associated with the reference handle, then the **vhpi_iterator()** shall return NULL. A NULL can be expected for one-to-many relationships that are marked with a multiplicity of * (zero or more) in the information model. The iterator handle is automatically released at the end of an iteration when there is no more elements to be returned by *vhpi_scan*. Reference to the iterator handle after the end of an iteration is erroneous. The iterator handle should be explicitly released with *vhpi_release_handle* if the iteration has not been exhausted in order to avoid a memory leak.

Example:

```
void find_signals(scopeHdl)
vhpiHandleT scopeHdl; /* a handle to a scope */
{
    vhpiHandleT sigHdl, itrHdl;

    /* find all signals in that scope and print their names */

    itrHdl = vhpi_iterator(vhpiSigDecl, scopeHdl);
    if (!itrHdl) return;
    while (sigHdl = vhpi_scan(itrHdl)) {
        vhpi_printf("Found signal %s\n", vhpi_get_str(vhpiNameP, sigHdl));
    }
}
```

11.23 vhpi_protected_call()

vhpi_protected_call()			
Synopsis:	Executes an operation on a shared variable of a protected type		
Syntax:	vhpi_protected_call(varHdl, userFct, userData)		
Type		Description	
Returns:	PLI_INT32	Returns 0 on success, non zero on failure.	
Type		Name	Description
Arguments:	vhpiHandleT	varHdl	A handle to a shared variable declaration of a protected type
	vhpiUserFctT	userFct	The user function pointer to be called during the protected access
	PLI_VOID *	userData	The user data to be passed to the user function
Related functions:	typedef PLI_INT32 (*vhpiUserFctT)(); The prototype of the user function should be: PLI_INT32 userFct(vhpiHandleT varHdl, PLI_VOID *userData) varHdl: reference handle of the vhpi_protected_call function. userData: user data to be passed to the userFct, can be NULL.		

vhpi_protected_call() shall be used to perform an operation to a shared variable of a protected type. The function guarantees atomicity of the operation by performing a lock on the variable passed as a reference handle.

vhpi_protected_call() should acquire a lock on the shared protected type variable passed as a reference handle, *varHdl*, execute the user function passed as a second argument, *userFct*, then release the lock on the protected variable handle. **vhpi_protected_call()** returns 0 on success and non zero on failure.

The lock performed is equivalent to the lock defined in the VHDL LRM 1076-2001. The kind of the reference handle that is passed to **vhpi_protected_call** should only be a handle denoting a shared variable declaration of a protected type. Handles and access to local objects defined in the protected type body associated with a shared variable can be performed within the user function where a variable lock has been acquired. If **vhpi_protected_call** fails to obtain a lock, it shall return a status of failure. **vhpi_protected_call** allows correct locking semantics of shared variable. If read or write access to a shared variable of a protected type is not made within a call to **vhpi_protected_call()**, the results may be erroneous.

Francoise: redo the example to access a private data declaration of the variable.

Example:

```
#include <stdio.h>
#include vhpi_user.h

/* user function which is called on the protected variable handle */
int Myfunc( vhpiHandleT protectedVarDeclHdl, void* ClientData )
{
    #define FAIL -1;
    int status=0;
```

```

1     vhpiHandleT resultH;
2
3     MyData* Data=(MyData*)ClientData;
4     /* result is a private variable declaration for the protected type */
5     resultH = vhpi_handle_by_name("result", protectedVarDeclHdl);
6     if (!resultH)
7         return (FAIL);
8
9     /* access the current value of result */
10    status = vhpi_get_value( result, Data->Value );
11    if (status)
12    {
13        vhpi_printf("error in reading protected variable\n");
14        return (status);
15    }
16    switch(Data->Op)
17    {
18        case op1 : op1CB( Data->Value);break;
19        case ....
20        case
21        default: Bombout();
22    }
23    /* set result to a new value */
24    status = vhpi_put_value( resultH, Data->Value, vhpiDeposit );
25
26    /* do some more error checking */
27    if (status)
28        vhpi_printf("error in writing to protected variable\n");
29
30    return status;
31 }
32
33 /* the proposed function for controlling protected variables access
34 This function is implemented by the VHDL simulator and VHPI interface */
35
36 int vhpi_protected_call(
37     vhpiHandleT protectedVarDeclHdl,
38     int (*Myfunc)(vhpiHandleT protectedVarDeclHdl,void* ClientData),
39     void* ClientData )
40 {
41
42     int status;
43
44     /* acquire the lock on the protected variable */
45     int Lock = internal_getlock(protectedVarDeclHdl);
46     /* do some error checking to determine if the lock was */
47     /* obtained ok */
48
49     /* then executes the user function passed in */
50     status = Myfunc( protectedVarDeclHdl, ClientData );
51
52     /* release up the lock */
53     internal_releaselock(Lock);
54
55     /* return the user function status */
56     return status;
57 }
58
59
60

```

```

1  /* in user code */
2
3  int op1CB( int value )
4  {
5      ...
6  }
7
8  main (argc, argv)
9  {
10 /* get a handle to the protected variable declaration named "Foo" */
11 vhpiHandleT protectedvarDeclHdl = vhpi_handle_by_name( "Foo", NULL);
12
13 MyData Data;
14 int status = 0;
15
16     Data.Op = op1;
17     Data.Size = 100;
18     bzero(Data.Value, Data.Size );
19
20     status = vhpi_protected_call(protectedVarDeclHdl, Myfunc, Data);
21
22     if (status)
23         vhpi_printf("Unable to perform operation op1
24                     with protected variable Foo\n");
25 }

```

11.24 *vhpi_printf()*

vhpi_printf()			
Synopsis:	Write to whatever files were defined by the tool to be the message display files (for example stdout, simulator log files)		
Syntax:	vhpi_printf(format, ...)		
Type		Description	
Returns:	PLI_INT32	The number of characters written	
Type		Name	Description
Arguments:	const PLI_BYTE8 *	format	A format string
	...	args	Arguments for the formatted string
Related functions:	VHPI_GET_PRINTABLESTRCODE() vhpi_is_printable_char()		

vhpi_printf shall write to the files that were defined by the tool to receive output messages. Such files could be stdout, the tool log file for example... The format string shall use the same formats as the C printf. The function shall return the number of characters printed or EOF (-1) if an error occurred. In order to print the VHDL non graphic characters that can be found in VHDL string literals or value of type VHDL string, VHPI provides a macro **VHPI_GET_PRINTABLE_STRINGCODE** to get the string corresponding to the enumerated character value defined in the standard VHDL character type set. A function to test if a character is a graphic or non graphic character is also provided **vhpi_is_printable()**. The example below shows how to print a VHDL string which may contain non graphic characters using the macro and table look up included in the `vhpi_user.h` file.

Example:

From `vhpi_user.h`

```
#include <stdio.h>
```

```

54 HELLO & NUL & C128 & DEL
55 is
56 HELLO,NUL,C128,DEL
57

```

11.25 *vhpi_put_data()*

vhpi_put_data()			
Synopsis:	Save data to a simulation save location.		
Syntax:	vhpi_put_data(PLI_INT32 id, PLI_VOID *dataLoc, PLI_INT32 numBytes)		
	Type	Description	
Returns:	PLI_INT32	the number of bytes saved or 0 on error	
	Type	Name	Description
Arguments:	PLI_INT32	id	an identifier denoting a position in a saved location
	PLI_VOID *	dataLoc	the address of the data to be saved.
	PLI_INT32	numBytes	the number of bytes to write out.
Related functions:	Use <i>vhpi_get_data()</i> to read data from a saved location Use <i>vhpi_get(vhpiIdP, NULL)</i> to get a new unique id.		

vhpi_put_data() shall be used to store “numBytes” of data located at “dataLoc” into a simulation saved location. The return value will be the number of bytes successfully saved. Id is a unique identifier for the simulation session that denotes a reserved area in the simulation save location. **vhpi_get(vhpiIdP, NULL)** shall be used to obtain a new unique identifier. The returned unique id denotes an index position that is used to refer to a reserved area in a simulation save location. This function shall be called during the save operation. The id returned is a non null integer. Each call to *vhpi_get(vhpiIdP, NULL)* will generate a new id.

There is no restriction on:

- * how many times **vhpi_put_data()** can be called with the same “id”,
- * how many “id”s a foreign model or an application creates,
- * the order foreign models or applications store data using different “id”s.

The data from multiple calls to **vhpi_put_data()** with the same “id” must be stored by the simulator in a way that the opposite routine **vhpi_get_data()**, for the same id, will retrieve data in the order it was put in the save location. This allows the **vhpi_get_data()** function to pull the data stored in the save file from different “ids” corresponding to different save location index positions.

vhpi_put_data() can only be called from a callback routine which was registered for reason *vhpiCbStartOfSave* or *vhpiCbEndOfSave*.

Example: A consumer routine which saves data to a simulation save location and registers callback to restore the data.

See also the example in **vhpi_get_data()** for the description of the restart callback function.

```
/* type definitions for private data structures to save used by the
foreign models or applications */
struct myStruct{
    struct myStruct *next;
    int d1;
    int d2;
}
void consumer_save(vhpiCbDataT *cbDatap)
{
    char *data;
    vhpiCbDataS cbData; /* a cbData structure */
```

```

1   int cnt = 0;
2   struct myStruct *wrk;
3   vhpiHandleT cbHdl; /* a callback handle */
4   int id = 0;
5   int savedBytesCount = 0;
6   /* get the number of structures */
7   wrk = firstWrk;
8   while (wrk)
9   {
10      cnt++;
11      wrk = wrk->next;
12  }
13  /* request an id */
14  id = vhpi_get(vhpiIdP, NULL);
15  /* save the number of data structures */
16  savedBytesCount = vhpi_put_data(id, (char*)&cnt, sizeof(int);
17  /* reinitialize wrk pointer to point to the first structure */
18  /* save the different data structures, the restart routine will have
19     to fix the pointers */
20  while (wrk)
21  {
22      savedBytesCount += vhpi_put_data(id, (char *)wrk, sizeof(struct
23 myStruct));
24      wrk = wrk->next;
25  }
26  /* check if everything has been saved */
27  assert(savedBytesCount == 4 + cnt * (sizeof(struct myStruct)));
28  /* now register the callback for restart and pass the id to retrieve
29     the data, the user_data field of the callback data structure is
30     one easy way to pass the id to the restart operation */
31  cbData.user_data = (void *)id;
32  cbData.reason = vhpiCbStartOfRestart;
33  cbData.cb_rtn = consumer_restart; /* see example in vhpi_get_data()
34                                     * for the description of
35                                     * consumer_restart
36                                     */
37  vhpi_register_cb(&cbData, vhpiNoReturn);
38  } /* end of consumer_save */
39

```

11.26 vhpi_put_value()

vhpi_put_value()			
Synopsis:	Update the value of an object, name or foreign function returned value		
Syntax:	vhpi_put_value(objHdl, valuep, flags)		
Type		Description	
Returns:	PLI_INT32	0 on success, non 0 on failure to change the value	
Type		Name	Description
Arguments:	vhpiHandleT	objHdl	Handle to an object of which the value can be changed
	vhpiValueT *	valuep	Pointer to a value
	PLI_UINT32	flags	Flags values defined in the enumeration type vhpiPutValueModeT
Related functions:	Use vhpi_get_value() to get an object to a value. Use vhpi_schedule_transaction to update the waveform of a signal driver.		

vhpi_put_value() shall update the value of an object. Classes to which this operation can be applied are either sub-classes of the class ObjDecl, Name or foreign function call. The function takes 3 arguments: **objHdl**, handle to the object to which the value update will be applied, **valuep**, pointer to a value structure that describes the value. The function returns 0 on success and non zero on failure to apply the value. The update can be done in several ways, the third parameter, **flags**, indicate which kind of immediate update is requested.

If the **flag** parameter is set to:

vhpiDeposit: the value is immediately applied with no force, no propagation, no event creation
no signal value change callbacks trigger; variable value change callbacks trigger
only readers of that object will see the new value.

vhpiDepositPropagate:

value is immediately applied, propagated only for this cycle.
may create an event or remove an event, signal value change callback may trigger if signal effective value is changed; variable value change callbacks trigger.

vhpiForce: (until release)

no propagation, no VHDL net can overwritethat value readers can see the value, no value change callbacks trigger.

Force callbacks trigger if the object value is forced.

vhpiForcePropagate

value is forced, propagated, can create or remove an event
Signal value change callbacks trigger if an event occurs on the signal.
Force callbacks trigger if the object value is forced.

vhpiRelease

The previous forced value is released, if the object was not forced, this has no effect. The value of

Deleted:

Formatted: Indent: Left: 0.5"

Deleted:

the object is then left to the network update. The pointer to the value structure valuep is not required when vhpi_put_value if called with the vhpiRelease flag. If a non null valuep pointer is provided, it will be ignored.

Formatted: Indent: First line: 0.5"

Release callbacks trigger if the object changed from a state of forced to released.

The property *vhpiIsForcedP* is true for an object that is being forced with **vhpi_put_value()** and the flag parameter was *vhpiForce* or *vhpiForcePropagate*.

The semantics related to modes and classes of the VHDL formal parameter interface declarations are carried on by foreign subprograms. Runtime errors should be generated if the VHDL rules are violated by the foreign C code; for example, one should not call *vhpi_put_value()* on a handle to a IN formal parameter, or try to get the value of an OUT formal parameter by calling *vhpi_get_value()*.

vhpiSizeConstraint

vhpi_put_value can be used to set the returned value of a foreign function call. If the function return type is unconstrained, a preliminary call to **vhpi_put_value** with a flag argument set to *vhpiSizeConstraint* will set the constraint of the returned value, the *numElems* field of the value parameter shall be set to the size of the constraint. The first argument must be a handle to the function call. The second call to **vhpi_put_value** will actually pass the value to be returned. The flag argument should be set to *vhpiDeposit*. If **vhpi_put_value** is used to provide the value of an unconstrained type object, it must first be called with *vhpiSizeConstraint* prior to setting the value.

11.27 *vhpi_register_cb()*

vhpi_register_cb()			
Synopsis:	Register a callback function for a specific reason		
Syntax:	vhpi_register_cb(cbDatap, flags)		
	Type	Description	
Returns:	vhpiHandleT	A handle to the callback object or NULL	
	Type	Name	Description
Arguments:	vhpiCbDataT *	cbDatap	Pointer to a structure with data about which and when callback should occur and data to be passed.
	PLI_UINT32	flags	defined constant value flags: <i>vhpiDisableCb</i> and <i>vhpiReturnCb</i>
Related functions:	Use <i>vhpi_remove_cb()</i> to remove the callback. Use <i>vhpi_get_cb_info</i> to get information about the given callback handle		

vhpi_register_cb() shall be used to register a callback for a specific reason. The reason is the condition of occurrence of the callback.

The *cbDatap* argument should point to a *vhpiCbDataS* structure that is defined in the VHPI standard header file. This data structure is allocated by the caller and should contain information about the callback to be registered. Depending on the reason, some fields of the *vhpiCbDataS* structure must be provided (refer to chapter 8). The *obj* field of *cbDatap* may be set to a handle; the client code is free to release that handle after the callback has been registered with no impact on the callback registration. If the flags field is set to *vhpiReturnCb*, the registration function shall return a callback handle, otherwise it shall return NULL. The callback can be set to a disabled state at the registration if the flags field is set to *vhpiDisableCb*.

Note: It is useful for a client application which disables the callback at the registration to also set the flags field to *vhpiReturnCb* so that it can retain the callback handle to enable it at a future time. Alternatively the client application can use the *vhpiCallbacks* iteration method in conjunction with the query property *vhpiStateP* to find the disabled callbacks.

When the callback function *cb_rtn*(const struct *vhpiCbDataS* **cbDatap*) triggers, the *cbDatap* is allocated by the VHPI server and is a read only data structure. The contents of the *cbDatap* passed in the callback function are equivalent to the content of the *cbDatap* structure which was passed at the callback registration to *vhpi_register_cb()*. Specifically if the *obj* field is set to a handle, it may not be the same handle which was set at the time of the registration. The entire *cbDatap* structure and its contents (including the handle) are owned by the VHPI server and are not guaranteed to be valid outside the callback function scope. In particular the client code shall not release the handle pointed by the *obj* field.

```
typedef struct vhpiCbDataS {
    int reason;          /* the reason of the callback */
    (void) (*cb_rtn)(const struct vhpiCbDataS *); /* the
                                callbackfunction pointer */
    vhpiHandleT obj;     /* a handle to an object */
    vhpiTimeT *time;    /* a time */
}
```

```

    vhpiValueT *value; /* a value */
    void *user_data;   /* user data information */

} vhpiCbDataT, *vhpiCbDatap;

```

Example 1: Register value change callbacks on all signals in the design

```

1
2
3
4
5
6 /* the callback function */
7 void vcl_trigger(cbDatap)
8 const vhpiCbDataT *cbDatap;
9 {
10 char *sigName;
11 int toggleCount = (int)(cbDatap->user_data);
12
13     cbDatap->user_data = (char *) (++toggleCount);
14     sigName= vhpi_get_str(vhpiFullNameP, cbDatap->obj);
15     vhpi_printf("Signal %s changed value %d, at time %d\n", sigName,
16                 cbDatap->value.int, cbDatap->time.low);
17     return;
18 }
19 static void monitorSignals(instHdl); /* this is the name of the
20                                     function which registers signal
21                                     value change callbacks */
22 vhpiHandleT instHdl; /* a handle to an instance */
23 {
24     /* monitors all signals in this instance */
25     static vhpiCbDataT cbData;
26     vhpiValueT value;
27     vhpiTimeT time;
28     int flags;
29
30     value.format = vhpiIntVal;
31     cbData.reason = vhpiCbValueChange;
32     cbData.cb_rtn = vcl_trigger;
33     cbData.value = &value; cbData.time = &time;
34     cbData.user_data = 0;
35     flags = 0; /* do not return a callback handle and do not disable the
36 callback at registration */
37 /* register the callback function */
38     sigIt = vhpi_iterator(vhpiSigDecls, instHdl);
39     if(!sigIt) return;
40     while(sigHdl = vhpi_scan(sigIt))
41     {
42         cbData.obj = sigHdl;

44     }
45 }
46

```

11.28 vhpi_register_foreignf()

vhpi_register_foreignf()			
Synopsis:	Register foreign architecture/procedure/function/application related functions		
Syntax:	vhpi_register_foreignf(foreignDatap)		
Type		Description	
Returns:	vhpiHandleT	A handle to the callback object.	
Type		Name	Description
Arguments:	vhpiForeignDataT *	foreignDatap	Pointer to a structure with data about which and when elab and execution functions should occur and data to be passed.
Related functions:	Use vhpi_register_cb() to register other reason callbacks for simulation events. Use vhpi_get_foreignf_info() to get information about which functions were registered for a particular model.		

vhpi_register_foreignf () shall be used to register foreign C functions for foreign architecture elaboration and initialization, procedure, function or application execution. The functions registered correspond to the C behaviour to invoke when a foreign architecture is encountered during elaboration of the VHDL code or when a foreign architecture, procedure, function or application is executed during simulation of the VHDL design.

The foreignDatap argument should point to a vhpiForeignDataT structure that is defined in the VHPI standard header file. This data structure contains information about the elaboration or execution functions.

```
typedef struct vhpiForeignDataS {
    vhpiForeignT kind; /* the foreign model class kind:
                        vhpi[Arch,Proc,Func]F */
    char *libraryName; /* the library name that appears in the
                        VHDL foreign attribute string */
    char *modelName; /* the model name that appears in the
                     VHDL foreign attribute string or
                     application name PA 28*/
    void (*elabf) ( const vhpiCbDataT * );
                  /* the callback function pointer for
                     elaboration of foreign architecture */
    void (*execf) ( const vhpiCbDataT * );
                  /* the callback function pointer for
                     initialization/simulation execution of
                     foreign architecture, procedure,
                     function or application */
} vhpiForeignDataT, *vhpiForeignDatap;
```

This data structure contains the mapping between a given foreign model and the C functions which implement the foreign model behaviour. The data is described below:

The *kind* field should register the foreign model to be an architecture, a procedure, a function or an application. The *kind* field value should be one of the following enumeration constants: **vhpiArchF**, **vhpiProcF**, **vhpiFuncF**, **vhpiAppF**.

The *libraryName* and *modelName* are respectively the library logical name and model name that are found in the VHPI foreign attribute string for foreign architecture and subprograms and the library and application names for a foreign application.

The *elabf* and *execf* fields should be pointers to the user-defined functions.

The function pointed by the *elabf* field will be invoked during elaboration of the foreign model. The function pointed by the *execf* field will be invoked during simulation initialization and/or execution of the foreign model or application. For foreign architectures, the *execf* function call occurs **once** during simulation initialization. For foreign procedures or functions, the *execf* function call occurs **each time** the VHDL corresponding procedure or function is invoked during simulation. For a foreign application, the *execf* function is called once before `vhpiCbStartOfTool` if the tool has determined that this application must be activated in this session. The determination of which applications must be activated is tool specific.

vhpi_register_foreignf() returns a handle to the model registered functions. The handle is of type **vhpiForeignfK**. The function **vhpi_get_foreignf_info()** shall be used to retrieve the foreign model information that was registered for a given foreign model or application. The VHPI method **vhpiForeignfs** can be used to iterate over all the registered foreign models and applications in a given tool session; the reference handle passed in should be null.

The following example illustrates how a user can dynamically link foreign model function callbacks.

Example:

```
void dynlink(foreignName, libName)
char * foreignName; /* name of the foreign model to link in */
char * libName;      /* logical name of the C dynamic library where the
                      model resides */
{
    static vhpiForeignDataT archData = {vhpiArchF};
    char dynLibName[MAX_STR_LENGTH];
    char platform[6];
    char extension[3];
    char fname[MAX_STR_LENGTH];
    char elabfname[MAX_STR_LENGTH];
    char execfname[MAX_STR_LENGTH];

    sprintf(platform, getenv("SYSTYPE"));
    if (!strcmp(platform, "SUNOS"))
        strcpy(extension, "so");
    else if (!strcmp(platform, "HP-UX"))
        strcpy(extension, "sl");

    sprintf(dynLibName, "%s.%s", libName, extension);
    sprintf(fname, "%s", foreignName);
    sprintf(elabfname, "elab_%s", foreignName);
    sprintf(execfname, "sim_%s", foreignName);
    archData->libraryName = libname;
    archData->modelName = fName;
    /* find the function pointer addresses */
    archData->elabf = (void(*)()) dynlookup(dynLibName, elabfName);
    archData->execf = (void(*)()) dynlookup(dynLibName, execfName);

    vhpi_register_foreignf(&archData);
}
```

This next example illustrates how to write a bootstrap function for a library of models. This bootstrap function can be called just after the VHDL tool (elaborator or simulator) has been invoked. It registers all the models defined in the C library at once. One way of writing this bootstrap function is to have an internal library table of **vhpiForeignDataS** structures. An entry in that table corresponds to a C model in the library, then the bootstrap function just needs to iterate through the entries in that table, and for each entry, call **vhpi_register_foreignf()**. The developer of the library has also the possibility to separate the registration of his models into several bootstrap functions.

Example 2:

```
extern void register_my_C_models(); /* this is the name of the bootstrap
function that must be the ONLY
visible symbol of the C library.
*/

void register_my_C_models()
{
    static vhpiForeignDataT foreignDataArray[] = {
        {vhpiArchF, "lib1", "C_AND_gate", "elab_and", "sim_and"},
        {vhpiFuncF, "lib1", "addbits", 0, "ADD"},
        {vhpiProcF, "lib1", "verify", 0, "verify"},
        0
    };
    /* start by the first entry in the array of the foreign data structures
    */
    vhpiForeignDatap foreignDatap = &(foreignDataArray[0]);
    /* iterate and register every entry in the table */
    while (*foreignDatap)
        vhpi_register_foreignf(foreignDatap++);
}
```

Errors:

The registration of a foreign model fails:

- if the required information is not present,
- if the library name/model name pair is not unique.

11.29 vhpi_release_handle()

vhpi_release_handle()			
Synopsis:	Release handle reference, free any memory allocated for this handle		
Syntax:	vhpi_release_handle(hdl)		
	Type	Description	
Returns:	PLI_INT32	0 on success, 1 on failure	
	Type	Name	Description
Arguments:	vhpiHandleT	hdl	Handle to an object

vhpi_release_handle() can be used by an application to tell the VHPI interface that it does not intend to reference and use the passed handle any more. Some implementations may free the memory that they had allocated to construct this handle in the case where the handle does not refer to an internal simulation or elaboration internal object. This function can be used for handles obtained from the navigation functions, callback registration, transaction scheduling. The function returns 0 on success and 1 on failure.

Example:

```

vhpiHandleT rootHdl, itrHdl;

rootHdl = vhpi_handle(vhpiRootInst, null);
itrHdl = vhpi_iterator(vhpiInternalRegions, rootHdl);
if (itrHdl) {
    while (instHdl = vhpi_scan(itrHdl)) {
        vhpi_printf("found sub-scope %s\n",
                    vhpi_get_str (vhpiName, instHdl));
    }
}
itrHdl = vhpi_iterator(vhpiInternalRegions, rootHdl);
if (itrHdl) {
    while (instHdl = vhpi_scan(itrHdl)) {
        if (vhpi_get(vhpiKindP, instHdl) == vhpiBlockStmtK)
            break;
        /* free this instance handle */
        vhpi_release_handle(instHdl);
    }
}

```

11.30 *vhpi_remove_cb()*

vhpi_remove_cb()			
Synopsis:	Remove a callback that was registered using <i>vhpi_register_cb()</i> .		
Syntax:	vhpi_remove_cb(cbHdl)		
Type		Description	
Returns:	PLI_INT32	0 on success, 1 on failure.	
Type		Name	Description
Arguments:	vhpiHandleT	cbHdl	A callback handle of kind <i>vhpiCallbackK</i>
Related functions:	Use <i>vhpi_register_cb()</i> to register a callback		

vhpi_remove_cb () shall be used to remove a callback that was registered using *vhpi_register_cb()*. The argument to this function should be a handle to the callback. The function returns 0 on success and 1 on failure. After the callback has been removed, the callback handle becomes invalid (the interface implicitly free the memory that was allocated for the callback including the callback handle).

Example:

```

int find_cbk(objHdl)
vhpiHandleT objHdl; /* a handle to an object */
{
    vhpiHandleT cbHdl, cbItr;
    vhpiCbDataT cbdata;
    int found = 0;

    /* find a specific callback on value change that was registered for that
    object and remove it */

    cbItr = vhpi_iterator(vhpiCallbacks, objHdl);
    if (!cbItr) return;
    while (cbHdl = vhpi_scan(cbItr)) {
        vhpi_get_cb_info(cbHdl, &cbdata);
        if (cbdata.user_data == 2) {
            vhpi_remove_cb(cbHdl);
            found = 1;
            vhpi_release_handle(cbItr); /* free the iterator */
            break;
        }
    }
    return(found);
}

```

11.31 vhpi_scan()

vhpi_scan()			
Synopsis:	Scan the VHDL model for objects in a one-to-many relationship with the reference handle indicated by the iterator handle		
Syntax:	vhpi_scan(iterHdl)		
Type		Description	
Returns:	vhpiHandleT	A handle on success, NULL if no objects of the type and reference handle indicated by the iterator exists.	
Type		Name	Description
Arguments:	vhpiHandleT	itrHdl	An iterator handle created by vhpi_iterator()
Related functions:	Use vhpi_iterator() to get an iterator handle		

vhpi_scan () shall be used to obtain handles to objects that are in a one-to-many relationship with the reference handle indicated by the iterator handle passed in. The **vhpi_scan()** function returns NULL when there is no more handle that comply to the iterator. The iterator handle is automatically released at the end of the iteration. References to the iterator after the end of an iteration are erroneous. If the iteration is not exhausted, the user should explicitly release the iterator to avoid a memory leak.

Example:

```

void find_signals(scopeHdl)
vhpiHandleT scopeHdl; /* a handle to a scope */
{
    vhpiHandleT sigHdl,itrHdl;
    /* find all signals in that scope and print their names */
    itrHdl = vhpi_iterator(vhpiSigDecl, scopeHdl);
    if (!itrHdl) return;
    while (sigHdl = vhpi_scan(itrHdl)) {
        _vhpi_printf("Found signal %s\n", vhpi_get_str(vhpiNameP, sigHdl));
        /* done with handle */
        vhpi_release_handle(sigHdl);
    }
}

```

Deleted: hpiHandleT

Deleted: int found = 0;

11.32 vhpi_schedule_transaction()

vhpi_schedule_transaction()			
Synopsis:	Schedule transactions on drivers		
Syntax:	vhpi_schedule_transaction(hdl, valuep, numValues, delayp, delayMode, pulseRefp)		
Type		Description	
Returns:	PLI_INT32	0 on success, non zero on failure.	
Type		Name	Description
Arguments:	vhpiHandleT	hdl	A handle to a driver or a drivercollection if routine is used to schedule a transaction
	vhpiValueT **	valuep	Array of pointer to values for the driver transaction
	PLI_UINT32	numValues	Number of values in valuep
	vhpiTimeT *	delayp	Relative time delay for the transaction
	PLI_UINT32	delayMode	Delay mode to apply
	vhpiTimeT *	pulseRejp	Pulse rejection limit for inertial mode
Related functions:	Use vhpi_put_value to change the effective value of a signal.		

vhpi_schedule_transaction() shall be used to schedule a transaction on a driver. The function can only be called during process execution phase. The transaction can be scheduled with zero or non-zero delay and with inertial or transport mode. To schedule a value on a driver requires to get a handle to a driver, **hdl**, of the signal, specify a value pointer, **valuep**, the number of values, **numValues**, a delay, **delayp** and delay mode, **delayMode**.

The delay modes that are supported are **vhpiInertial** and **vhpiTransport**. In the case of inertial delays, a user could specify an additional optional parameter, the pulse rejection limit that should be passed in **pulseRej** argument.

The value pointer could be

1. a pointer to a single value in the case of a scalar driver or a composite driver
2. a pointer to several values in the case of a composite driver.

There is no correspondance between the number of drivers in the driverCollection and the number of values structures passed in.

Note: scheduling transaction for drivers of composite type not resolved at the composite level, such as bit vectors, standard logic vectors, record types must be done by scheduling individual transactions on each scalar driver (see example 1) or by scheduling a transaction on a collection composed of these drivers.

Transaction for driver of signals resolved at the composite level must be scheduled at once; the user must allocate as many as value structures that are necessary for scheduling a transaction on the composite. The format and corresponding union value field must be set for each value structure. The space for holding each individual value (value union field of each individual vhpiValueS structure) must be allocated by the user in accordance with the chosen format. The next argument, **numValues**, indicates how many values are provided by **valuep**.

In general there will not be any VHPI check that all values have been actually allocated and set but the simulator may issue an error for case 2 if the composite driver is not assigned as a whole.

There will be a check that the specified format is allowed.

The array of values follows the order defined by the LRM for array or record aggregates.

1 The format of the specified value must be appropriate with the VHDL type of the driver as defined in
2 chapter 9. For example, if the driver type is standard logic, the format cannot be `vhpiRealVal`.
3 Runtime type errors shall occur if the provided value is not within the range of the driver subtype. The
4 execution of a *vhpi_schedule_transaction* involves runtime constraint type checking but does not
5 guarantee that the operation had no effect.
6
7 The pulse rejection limit is specified by a time structure. If the simulator is VHDL'87 compliant, it may
8 ignore the pulse rejection limit. The VHPI interface should warn the application that this pulse time
9 rejection is being ignored.
10
11 NULL transactions can be posted by setting *valuep* to a NULL pointer.
12
13 The specified delay is a relative delay and is specified by using the time structure *vhpiTimeS* to providing a
14 64 bits value.
15 Francoise: Since all time value are always expressed in terms of the resolution limit, how can it be possible
16 to indicate a time value smaller than the resolution limit? The delay value is truncated if smaller than the
17 VHDL simulator resolution limit. The delay value must be legal as if it were the delay value of a VHDL
18 signal assignment.
19 Zero delay transactions are specified by setting the low and high fields of the time structure to 0.
20
21 Scheduling a 0 delay transaction is only allowed during non postponed process execution and any callback
22 which occur during the non postponed process execution phase:
23 i) `vhpiCb(Rep)StartOfProcesses`
24 ii) `vhpiCb(Rep)TimeOut`
25 iii) `vhpiCbSensitivity`
26 iv) `vhpiCbStmt`,
27 v) `vhpiCbResume`
28 vi) `vhpiCbSuspend`
29 vii) `vhpiStartOfSubpCall`
30 viii) `vhpiEndOfSubpCall`
31 ix) `vhpiCb(Rep)LastKnownDeltaCycle`
32 x) `vhpiCb(Rep)EndOfProcesses`
33
34 Non-zero delay transactions can be scheduled during non postponed and postponed process execution and
35 any callback which occur during the non postponed and postponed process execution phase:
36 i) `vhpiCb(Rep)StartOfProcesses`
37 ii) `vhpiCb(Rep)EndOfProcesses`
38 iii) `vhpiCb(Rep)TimeOut`
39 iv) `vhpiCbSensitivity`
40 v) `vhpiCbStmt`,
41 vi) `vhpiCbResume`
42 vii) `vhpiCbSuspend`
43 viii) `vhpiStartOfSubpCall`
44 ix) `vhpiEndOfSubpCall`
45 x) `vhpiCb(Rep)LastKnownDeltaCycle`
46 xi) `vhpiCb(Rep)StartOfPostponed`
47 x) `vhpiCb(Rep)EndOfPostponed`
48
49 Non-zero delay transaction scheduling must occur before `vhpiCbEndOfTimeStep`, effectively before the
50 next time is computed. Scheduling a transaction at any other phase has no effect and may generate an error.
51 All zero delay transactions will be scheduled for the next delta cycle and all other delay transactions will be
52 scheduled for the time that corresponds to the current simulation time added to the specified relative delay.
53
54 Example 1: Recursive function which schedules a transaction on a signal.

```

1  The code of this function is incomplete: the case describes an unresolved record with a bit and a bit vector
2  members.
3  .
4  Iteration on vhpiSelectedNames obtain a handle to each record member. For the scalar bit field, schedule a
5  transaction on the single scalar driver. For the bit vector field, iterate on vhpiIndexedNames to get a handle
6  to each bit element of the bit vector field, then use the driver iteration to obtain a driver of each bit element.
7  Create a collection of the drivers and then schedule a bit vector value transaction on the collection.
8
9

6         return (-1);
7     break;
8 }
9 }

```

10

11 The VHPI interface should report an error if:

12 1. A negative relative delay is provided

13 Issue: if the times structure only contains UINT, it is not possible to specify a negative value.

14 2. The value given is not compatible with the signal base type.

15 3. The driver handle used to schedule an update is NULL.

16 4. The pulse rejection limit is greater than the inertial delay that is provided.

17 5. A zero delay transaction is attempted to be scheduled within the postponed process execution phase.

18 6. The handle passed in does not denote a driver.

19

Property access	Obtains a handle to an indexed element	vhpi_handle_by_index()	vpi_handle_by_index()
	Obtains a handle to a multi-index element	vhpi_handle_by_index()	vpi_handle_by_multi_index()
	Obtains a handle to multi handles	vhpi_handle_multi()	vpi_handle_multi()
	Returns value of integer property	vhpi_get()	vpi_get()
	Returns value of string property	vhpi_get_str()	vpi_get_str()
Value access and modifications	Returns value of a physical property	vhpi_get_phys	NA
	Returns value of real property	vhpi_get_real()	NA
	Gets the value of an object	vhpi_get_value()	vpi_get_value()
	Forces or schedules a zero delay value on an object	vhpi_put_value()	vpi_put_value()
	Schedule a future or zero delay transaction	vhpi_schedule_transaction()	vpi_put_value()
Callbacks	Get a delay value	NA	vpi_get_delays()
	Protected type access	vhpi_protected_call()	NA
	Modify a delay value	NA	vpi_put_delays()
	Registers a callback	vhpi_register_cb()	vpi_register_cb()
	Removes a callback	vhpi_remove_cb()	vpi_remove_cb()
C Foreign function	Enables a callback	vhpi_enable_cb()	vpi_enable_cb()
	Disables a callback	vhpi_disable_cb()	vpi_disable_cb()
	Gets callback info	vhpi_get_cb_info()	vpi_get_cb_info()
	Registers a foreign function	vhpi_register_foreignfn()	vpi_register_systf()
	Gets foreign function info	vhpi_get_foreignfn_info()	vpi_get_systf_info()
	Create a new elaborated object	vhpi_create()	vpi_create()
	Save data in a file	vhpi_put_data()	vpi_put_userdata()
	Restore data from file	vhpi_get_data()	vpi_put_userdata()

Table 1: Correspondence between VHPI and VPI functions

13. Annex A (normative) VHPI header file

```

1  The header file should be included by any application intending to use VHPI. This header file should be
2  provided by tool vendors supporting the VHPI interface.
3  The range of values from of 1000 to 2000 are RESERVED by the standard.
4  Vendors are allowed to provide additional functionality (other than the one defined by the standard) and
5  incorporate it in the header. This can be done by defining the following macros.
6
7  Note: INT_AMS * macros are place holders for VHPI ams extensions.
8
9
10 /* define internal macros for VHPI internal functionality */
11 #ifndef VHPI_INTERNAL_H
12 #define INT_CLASSES
13 #define INT_AMS_CLASSES
14 #define INT_ONE_METHODS

14. ANNEX B: Description of properties

14.1 Integer properties

vhpiLineNoP:

returns the line number in the source file of the item designated by the handle.

For a vhpiRootInstK: the line number of the architecture identifier.

For a vhpiPackInst, the line number of the package identifier of the package body.

For all the other region derived classes, the line number of the first word which starts the region instance.

For the decl class, the line number of the declared identifier

vhpiLineOffsetP:

returns the character offset from the beginning of the line of the designated item

Note: Not all classes that have the line number property (vhpiLineNoP) have the line offset

property

vhpiStartLineNoP: Applies only to the design unit class, returns the line number in the source where the design unit starts (includes the line number of the library and use clauses)

vhpiEndLineNoP: returns the line number of the end keyword in the VHDL text source.

vhpiBeginLineNoP: returns the line number of the begin keyword in the VHDL text source.

14.2 String properties

vhpiNameP:

This property returns the name of the designated object in unspecified case for basic identifiers (VHDL is case insensitive) or case preserved for extended identifiers:

- for a declared item, the declared identifier,
- for a component instance statement, block stmt: the label instance name,
- for a generate statement, the <label_name>(generate index)
- for a process stmt, the label of the process if specified or a created process label name (see rule below),
- for a VHDL name (see name class diagram) the VHDL string name as it appears in the VHDL text source with or without case preserved depending if there is reference to an extended identifier within the name.

Example: selected name: "f.a", indexed name: "r(j)"

Naming of unlabelled equivalent processes:

the VHPI would generate an equivalent process label name which starts by the concatenation of the "_P" or "_p" string and an integer which denotes the sequence appearance number of the equivalent process in the VHDL source text of the declared region. The numbering starts at 0 and increments by 1. For example the auto-generated vhpiNameP of the first equivalent process statement in an entity declaration would be "_p0". Numbering of equivalent processes in the architecture follows the numbering sequence used for the entity. The number used for the first process in the architecture will be either 0 if the entity did not contain any unlabelled processes or n+1 where n is the number used for naming the last unlabelled equivalent process of the entity. Numbering of processes is reset for each internal region (block, generate or component statement).

example: "_2" is the vhpiNameP of the second occurring process for this entity/architecture pair.

note: "_2" is not a legal VHDL identifier (should be escaped) this ensures that this identifier is not used in the rest of the design.

vhpiFullNameP:

The vhpiFullNameP property should return the concatenation of the vhpiNameP strings of each instance or item found on the hierarchy path.

The character : is used between 2 successive names returned by vhpiNameP.

The vhpiFullNameP property provides a non-ambiguous, simplest and easiest way to name a "named entity" (in the VHDL sense) which belongs to a VHDL design.

The vhpiFullNameP property returns a string that is different from the strings returned by the standard attributes 'PATH_NAME' and 'INSTANCE_NAME'.

The vhpiFullNameP of the root instance is ".". This is sufficient to refer to a unique root, VHDL 93 and 98 only allow one top level design unit. If multiple top level units were going to be defined in future versions of the language, we could allow the hierarchical name to specify which tree of the design hierarchy the name has to be searched from.

example of full names when multiple roots are allowed

@<entity_name>(<arch_name>):<instance_name>...

Notes:

- 1) both the entity and architecture names are necessary to identify the root.
- 2) entity_name(arch_name) is optional if the design has only one top design unit but required if multiple roots.

Construction of full names for items declared in packages is defined as follow:

@<lib_logical_name>:<pack_name>:<declared_item_name>

1 Since VHDL is case insensitive, the case of the `vhpiFullNameP` string is not specified unless there is an
2 extended identifier.

3 Note: `vhpiFullCaseName` should be used to retrieve the hierarchical name with case preserved characters
4 for the declared items.

5

6 `vhpiCaseNameP`:
7 This property returns the case preserved string of the item declaration. The string returned will reflect
8 lower or upper case characters used in the identifier declaration. Note that for extended identifiers, or
9 unlabelled equivalent processes, the `vhpiCaseNameP` string will be exactly the same as the `vhpiNameP`
10 string.

11

12 `vhpiFullCaseNameP`:
13 The string returned is formed by the concatenation of each single `vhpiCaseNameP` string on the
14 hierarchical path to the designated object. The `':'` character is the delimiter between each simple case name.

15

16

17 Note: all these properties `vhpiNameP`, `vhpiCaseNameP`, `vhpiFullNameP` and `vhpiFullCaseNameP` apply to
18 the name class (see primary expression diagram).

19

20

21 `vhpiDefNameP`:
22 The returned string name identifies the path to the declared thing in the library.
23 This property only applies to the region class and returns in unspecified case unless it is an extended
24 identifier a string which identifies the library path name of the declared item which is bound to the
25 designated region.

26

27 for block, generate or component instance statement
28 `<lib_logical_name>:<entity_name>(<arch_name>)`
29 for a package instance:
30 `<lib_logical_name>:<pack_name>`
31 for a subprogram call depending where the subprogram definition is
32 `<lib_logical_name>:<entity_name>(<arch_name>):<subprogram_name>`
33 or
34 `<lib_logical_name>:<pack_name>:<subprogram_name>`

35

36 for a process stmt declared in an entity:
37 `<lib_logical_name>:<entity_name>:<process_label_name>`
38 for a process declared in an architecture:
39 `<lib_logical_name>:<entity_name>(<arch_name>):<process_label_name>`

40

41 Note: If the process is unlabelled, a `process_label_name` is constructed according to the rule mentioned in
42 the `vhpiNameP` description.

43

44 `vhpiUnitName`:
45 The name of the declared design unit in the VHDL source. This property is ONLY applicable to the
46 `designUnit` class.

47 The name is returned in unspecified case for basic identifiers or case-preserved for extended identifiers.
48 The `unitName` of a design unit of the following class is:

49 EntityDecl: `lib_name.entity_name`
50 Arch body: `lib_name.entity_name.arch_name`
51 PackDecl: `lib_name.pack_name`
52 Pack Body: `lib_name.pack_name:BODY`
53 note: all variations of upper and lower case letters for `BODY` are allowed.

54 Config: `lib_name.config_name`

55

1 vhpFileNameP
2 Physical file system path name of the VHDL source file where the item designated by the handle appears.
3 Property is applicable for every VHPI class kind that has a vhpLineNoP (line number property). Among
4 these are declared items, design units for example.
5

6 **14.3 Real properties**

7 **15. Annex : issues and resolutions**

8 **15.1 Creation of signal attributes with vhp_create**
9 Resolution: Cannot create signal attributes with vhp_create

10 **15.2 What does a foreign function is allowed to do (callback,**
11 **vhp_schedule_transaction ...)**
12 Resolution: No restriction on which callbacks can a foreign subprogram register.

13 **15.3 Modeling for wait in subprograms**
14 1) Open issue on restriction of foreign procedures to be non blocking, with dependency on elaboration of
15 declarative parts of subprograms. There is a problem with foreign subprograms registering callbacks.
16 Issue to be resolved in conjunction with elaboration of foreign subprograms declaration.part
17 Action: John: document analysis of problems
18 Françoise: Investigate what current interfaces allow :OMI, NCSIM-CIF, FLI/ do we know of
19 any models that needs this functionality, what are the current limitations.
20
21 Resolution: None of the current VHDL procedural interfaces support this functionality; nobody has
22 requested it. Seems a high cost for specification and implementation.

23 **15.4 Default process implied by a foreign architecture**
24 Resolution: no default implicit process.

25 **15.5 cancelling transaction and returning handle to a transaction bundle.**
26 Resolution: removed from the standard, no use

27 **15.6 Can vhp_put_value be called during initialization cycle?**

28 **15.7 Are vhpStartOfSubpCall and vhpEndOfSubpCall repetitive callbacks**
29 Resolved 1/18/01 YES repetitive and for a specific instance of the subprogram call
30

31 **15.8 Are save/restart and reset callbacks repetitive?**
32 Resolution: Save are repetitive until the end of simulation or a reset or restart command. Restart are not.
33 Reset are repetitive. Contradiction with the fact we say that at the reset all callbacks are removed.

34 **15.9 Representation of real physical literals 2.5 ns**
35 Resolved: physical literal diagram

36 **15.10 VhpLogicVal and vhpLogicVecval standard formats for logic types**
37 Resolved: added to the standard

1 **15.11 When a signal or a port is forced, what should vhpiContributors and**
2 **vhpiDrivers return?**

3 Resolved: should still return all the contributors and drivers

4 **15.12 Restart sequence**

5 Do we need to call again all the bootstrap functions? Including the application bootstrap?
6 (probably not since they should have register a restart callback which will be called at restart.
7 Unless requested explicitly at the tool invocation, the bootstrap functions or dynamically loaded library
8 will be processed.

9
10 Resolution: application should be saved/restart aware (no need to bootstrap them again).
11 Restart sequence has been approved
12

13 **15.13 Reset sequence**

14 Which callbacks are removed?

15 **15.14 CbAfterDelay callback**

16 callback cbAfterDelay what is the behaviour is delay is 0 ?

17 **15.15 CbStartOfPostponed callback**

18 callback cbStartOfPostponed is a phase callback and should occur whether or
19 not there is any postponed process waking up?
20

21 **15.16 vhpiDecl inheritance class**

22 Is missing vhpiDesignUnit. vhpiUses returns declarations referred by the use clause.

23 **15.17 Can vhpi_put_value be called during initialization cycle?**

24 Vish: Yes. We in fact use it during initialization. There is a problem with this though. We could discuss
25 this at our meeting. The problem is that the deposit should take effect immediately, as there is no concept
26 of the next delta cycle. What we do is that we do signal propagation only for all such updates. This is a
27 very useful feature, that we use with a flag that we call vhpiForceImmediate (which I think should really be
28 vhpiDepositImmediate, that does just the propagation without queuing processes for execution)
29

30 **15.18 Access to the component declaration from a component instance**
31 **statement**

32 Currently only the component declaration name is available for a component instance statement.
33 It is useful to be able to get to the real component declaration as this component declaration contain local
34 ports and generics with modes and initial expressions... A lint HDL tool may want to process some checks
35 on the component declaration. This component declaration may be declared in a package or in the
36 architecture which contains the component instance statement, this makes it difficult for an application to
37 find the matching the component declaration which was used for the component instance statement. I
38 propose we add a VHPI one to one method to return the component declaration.
39

40 **15.19 Access to the subprogram body from a subprogram declaration**
41

1 Currently the VHPI information model allows to go from a subpCall to its subpBody and from the
2 subpbody to its supDecl; this is not sufficient. It is not possible to go from a subpDecl to its subpBody.
3 Francoise to check the LRM to see if multiple subpBody can be associated with one subpDecl.
4

5 **15.20 When can you apply vhpi_schedule transaction**

6
7 Issue: We need to define when in the simulation cycle the cbAfterDelay and cbNextTimeStep callback
8 occurs: if these callback occur after transaction have been processed, when will the
9 vhpi_schedule_transaction take effect. Should vhpi_schedule transaction only allowed during process
10 execution? Any other phase would be undefined behaviour

11 Discussion:

12 cancelling transaction does not seem to be useful, it will be removed from the standard. Same effect can be
13 obtained by calling vhpi_schedule_transaction (and doing transaction preemption).
14

15 Vish pointed out that allowing 0 delay transaction at NextTimeStep or CbAfterDelay callbacks may be non
16 portable across simulators. Some simulators may schedule the transaction in the current delta cycle, some
17 may create a new delta cycle.

18 Resolution: We decided to only allow to schedule a 0 delay transaction during process execution and
19 cbLastKnownDeltaCycle, which will cause a new delta cycle to be created if the transaction generates an
20 event. non-zero delay transactions can be scheduled at any time before
21 cbEndOfTimeStep, effectively before the next time is computed.
22

23 **15.21 Collection of drivers**

24
25 Can you create collection of drivers for drivers of same signal , different processes
26

27 **15.22 What happen to Mature callbacks**

28
29 Mature callbacks should be handled consistent with the principles of resource ownership for VHPI clients.

30 When a callback matures, there
31 is no value to it except for query. It cannot be re-enabled, and it cannot
32 be discovered via traversal of the information model. It should be deleted
33 by the VHPI server, unless the client(user) has previously obtained a handle
34 to the transaction. If the client has a handle, he has ownership, albeit to
35 something of marginal value. He can query it or just waste the memory
36 resource. It follows that, after all such handles are released, the
37 mature transaction should be deleted. The VHPI server is free to waste
38 resources itself, but the point is, it has ownership of the transaction.
39

40 **15.23 Uninstantiated access: expanded names;**

41 The following statements were not approved by the committee.
42

43 The uninstantiated model should store an additional property, *IsExpanded*, on the *SelectedName* class
44 indicating whether it is an expanded name in the source file.
45

46 ISSUE: How to support this? FM is of the opinion that we should have a different class (OutOfModuleRef)
47 with Name and LineNo and a method vhpi_oomr_decl() that will get you to the object's declaration by
48 crossing the design unit. JB: It needs to be a derived object off name since any object, operator, procedure
49 name, type name, etc. can be an out-of-module reference.

After discussion, the resolution was to treat expanded names to declarations in other design unit the same way as names declared in the current design unit. This has the drawback to not being able for decompilation applications to exactly produce the original source. This is more efficient for synthesis oriented applications and more inline with the information retained by analyzers.

15.24 *vhpi_handle_by_name* returning collections

Description: A conceivable extension of *handle_by_name* is the support of regular expressions returning collections of handles.

Rationale: This is a powerful convenience function that can be built from current VHPI capabilities. It sets the requirements for compliance too high for the first version of the spec.

Resolution: This is out of the scope of VHPI.

15.25 *Associating Errors with VHPI Clients*

Description: There are methods of handling errors that occur during the use of VHPI, but there are situations where VHPI cannot determine which of multiple VHPI client applications or models caused a particular error. If one registers a callback on error, for example, VHPI will trigger it when an error occurs, regardless of what caused it. A desirable improvement is to call only the client that both caused the error and registered for such a callback. The problem is, there is no method to associate errors with a particular client, nor does VHPI maintain an association between client and its callbacks that would support this type of improvement.

There is a related problem, a corollary that says if you obtain a handle to a callback by navigating the information model, there is no straightforward way to examine it to see if it was your application that registered it. Both these problems are barriers to friendly VHPI applications that can peacefully coexist with each other.

Solution proposed:

One proposal to resolve it is to provide a mechanism that defines a unique client identity that can be associated with callbacks and, in general, with executing VHPI code. Since callbacks are the principle means by which a VHPI client's code gains control, VHPI has a means to track which client appears to be executing when it encounters an error. This is not a solid proposal yet, and questions remain whether this mechanism will fail to have a correct association in some important cases.

The basic idea is to have a *vhpi_client_registration* function that takes a string argument representing the name of the client and return a unique integer id each time it is called. This id is then provided with any callback registration made by the client. First, given a callback handle, the client can get the callback info and recognize its own unique id. Secondly, when VHPI dispatches a callback, it can "know" which client is running. Using that information, it can provide it as another part of the error structure when a errors are checked, it can choose to only call error callbacks that have been registered by that client, etc. We can certainly allow the notion of an anonymous client with a well known id (say "0"), and the unknown client whose id does not have a name associated with it. We can even allow an error callback to register for "any" client in a meaningful way.

Something to note is that it is not mandatory that a client have unique client id and this is not a means of securely isolating one application from another. It is meant as a practical way of writing more friendly VHPI applications. In order to enforce the use of a unique client id, one would have to require it to call any API function except the registration call itself. Worse, it may difficult in some simulator architectures for VHPI to know which client's code is executing in some cases. It is undesirable to require that VHPI clearly know which client caused a particular error. It is only generally required to know that the last *vhpi*

function call was responsible at this time. If there is a circumstance where the error is not detectable until after possibly many VHPI calls have occurred, the simulator may only know that some prior VHPI action led to the error condition.

Such cases are not intended to be covered by this proposal.

Resolution: At a minimum, the difficulty with using the error callback mechanism and possibly identifying your own callbacks must be stated in the spec. There is no desire to make a complete VHPI client server model or require client ids as arguments to each vhpi function.

15.26 *vhpiFullName same as 'path_name predefined attribute string?*

Issue: The `vhpiFullNameP` property is not returning the same string as either `'path_name` or `'instance_name`

The `vhpiFullNameP` property is intended to be an improvement on `'path_name` attribute of the language. It is meant to be minimal in string length. The idea behind minimizing the string length includes conserving real estate in user interfaces, printed reports. Choices like using `'path_name` vs. `'instance_name` as a starting point and eliminating the `rootInst` entity name derive from this goal.

It is reasonable to expect that a user will obtain names using both VHPI properties and the predefined VHDL attributes and provide them as input to VHPI-based applications or functions. With the `vhpiFullNameP` property, well-defined standard behavior can be expected of `vhpi_handle_by_name`. With the predefined attributes, under most conditions, a well-defined behavior will also occur if `vhpiFullNameP` is defined to be as consistent as possible to `'path_name`.

Not Handling Redundant Information In Lookups

VHPI could support another name property that is analogous to `X'INSTANCE_NAME`. The additional information (i.e., the `@e(a)`) is redundant information for the search and increases its cost. We propose that the information be accepted and verified in the search algorithm.

It is forward looking to consider this in the future, as VHDL requires that the instantiation label be unique within a scope but not all HDLs do.

Resolution: `vhpiFullNameP` property will have a different string than the predefined attributes to resolve ambiguities and to minimize the string length to be used for looking up the object of that name with `vhpi_handle_by_name`. We would provide two additional properties: `vhpiInstanceNameP` and `vhpiPathNameP` so that foreign models and applications can provide similar output similar as to the simulator using the `'instance_name` and `'path_name` attributes.

Issue: *Pathological Cases of Ambiguity*

VHDL syntax leaves room in its particular choice of namespaces and keywords for certain pathological problems. One of them is that the root entity name and a library logical name may be the same in some pathologically difficult elaborated design. Entity names like `work`, `IEEE`, etc. pose no conflict, even though those are also well known logical library names. The impact of this is that the first part of `'path_name` may refer to the root instance entity name or a logical library and you cannot distinguish between them.

I regard this as a pathological (vs. practical) problem in which a number of solutions are rationale.

1) You can define a search order and return the first one found (solution hides names in a predictable manner).

2) You can also search the entire space, verify the name is a duplicate, and diagnose the problem as an ambiguous reference.

3) You can allow or require an extended syntax to qualify whether you mean the packInst or the root instance. For example, you could require:e(a) to disambiguate and always attempt to search the packInsts before the root inst. Probably this is acceptable

Resolution: always precede a library name or package name by a @

There is another minor pathological problem, that of multiple logical libraries referring to the same physical library. VHPI should not make any statement that referring to an object through 2 or more logical library names in any way preserves that this is the same object.

15.27 Creation of foreign drivers

Requirement: Testbench tools need to be able to participate to the resolved value of signals, for that they need to be able to create their own drivers of the signal they are interestd in. Testbench tools often apply several different test sequence to a design, and may want to driver different signals each time. The test pattern if often generated after inspection and analysis of the design.

Issue: Elaboration phase creation of foreign drivers is too late.
When and how can we create foreign drivers?

16. ANNEX C: Formal textual definition of the VHPI information model

Class abstractLiteral

Superclasses: literal

```
{
  intLiteral
  realLiteral
}
```

Class accessTypeDecl

Superclasses: typeDecl

one-to-one relationships:
mult 1 subtype<-ValSubtype

Class aggregate

Superclasses: primaryExpr

Iteration relationships:
it mult 1..* elemAssoc<-elemAssoc

Class aliasDecl

```

1  Description:
2  This class represents alias declarations.
3  In case of non alias objects which are not character literals, the vhpiSizeP
4  property will return -1; the operation vhpi_get_value will return 0 because
5  the alias has no value.
6
7  Superclasses: decl, simpleName
8
9  Attributes:
10 p int -Size
11     size in scalars of a value of the object
12
13 one-to-one relationships:
14     mult 0..1 subtypeIndic<-Subtype
15     mult 1 name<-name returns the aliased object or range. Name can itself be an alias.
16 Operations:
17 #vhpi_get_value(handle: vhpiHandle, value: vhpi_value_p) : int
18     get the value of the object designated by the alias
19
20 -----
21
22 Class allLiteral

8  Class argv
9
10 Description:
11 A command line argument string separated by white spaces passed
12 to the tool.
13 This class mimics an element of the array of argv parameters that would
14 be passed to a C main routine.
15 A vendor is not required to give access to all the arguments passed on the
16 command line of the tool.
17
18 Superclasses: base
19
20 Attributes:
21 p string -StrVal
22   The string value of the argument as found on the command line
23 p bool -IsPLI
24   True if the argument is an argument which concerns VHPI. This is either for
25   VHPI interface to process and take some action or for a VHPI application to
26   process.
27   This property allows an application to test if it should process this command
28   line argument. Command line arguments have no special syntax for VHPI.
29
30 p int -Argc
31   number of args
32
33 Operations:

36   entityAspect
37   pragma
38   tool
39   argv
40   reference
41   spec
42   iterator
43   collection
44   driverCollection
45   anyCollection
46 }
47
48 Attributes:
49 p int -Kind
50   associates an integer constant (identifier) to each leaf class
51 p string -KindStr
52 p bool -IsInvalid
53   True if the handle is invalid: the object which the handle refers to ceases to
54   exist either because the object was dynamically elaborated,
55   or by virtue of a user action (removing a callback or transaction or because
56   the transaction matures.

```

1 If a handle is invalid, this is the only property that can be accessed. No
 2 other access is possible.
 3 p bool -IsUninstantiated
 4 If this property is TRUE then the handle represent uninstantiated VHDL data.
 5 This means that the data
 6 represented by this handle is pre elaboration (post-analysis) and does not
 7 contain any post
 8 elaboration information. In particular
 9 it is not possible to walk the instantiated design hierarchy from this handle
 10 or to get the value of this
 11 handle if that value can only be determined after elaboration. (may have a
 12 full name to be defined later in the uninstantiated access spec).
 13 If this property is FALSE, the handle represent post-elaboration VHDL data
 14 and full access to the VHPI instantiated (post-elaboration) model is allowed.
 15
 16 -----
 17
 18 Class basicSignal
 19
 20 Description:
 21 a basic signal according to the LRM definition page 165,
 22 The basic property is true for the classes derived from a basicSignal
 23 The vhpiEntityClassP property shall return vhpiSignalEC for a basic signal
 24 handle kind.
 25
 26 Superclasses: base
 27
 28 {
 29 sigDecl
 30 portDecl
 31 selectedName
 32 indexedName
 33 sliceName
 34 }
 35
 36 Attributes:
 37 p bool -IsBasic
 38 is it a basic signal?
 39 Explicit Guard signals can be basic signals; implicit guard signals cannot
 40 be.
 41 a slice is basic only if it denotes a an indexedName basic signal (slice is
 42 size 1) or if it denotes the entire slice of a resolved composite basic
 43 signal.
 44 p bool -IsResolved
 45 The basic signal is resolved if if a resolution function
 46 is associated with the declaration of that signal or in the declaration of
 47 the subtype of that signal (page 27 VHDL lrm 1076-93). A signal can be
 48 resolved at the sub-element subtype level.
 49
 50
 51 Iteration relationships:
 52 it mult * driver<-driver returns the drivers for the basic signal.
 53 note: a signal attribute is not a basic signal therefore you cannot iterate on drivers from a signal
 54 attribute. VHPI should generate an error.

46
47 Class contributor
48
49 Description:
50 a contributor to the value of a signal. A contributor can be a driver, a source
51 (port of a block with which the signal is associated), a conversion function
52 applied to a port which is connected to the signal, a type conversion, a static
53 expression, or a composite collection of sources.
54 Contributors to the IN value or to the OUT value of a port can be acquired.
55 note: a contributor can be a signal attribute 'active, 'quiet or 'transaction or
56 'delayed.

```

```

1  note: Iteration on contributors from the signal attributes handle should return
2  NULL and an error.
3  iteration on contributor from an implicit GUARD signal should return the guard
4  expression. Iteration on contributors from an explicit GUARD should return the
5  contributor of that GUARD.
6
7  Superclasses: base

8  typeDecl
9  subtypeDecl
10 unitDecl
11 elemDecl
12 subpBody
13 subpDecl
14 enumLiteral
15 charLiteral
16 }
17
18 Attributes:
19 p string -Name
20     the declaration name, unspecified case
21     if basic identifier or case - preserved if extended identifier
22     If the declaration denotes an anonymous type then the vhpNameP property
23     returns "$anonymous"
24 p string -CaseName
25     The case sensitive name of the declared item, Same restrictions as for
26     vhpNameP.
27 p string -FullName
28     full hierarchical from the top of the hierarchy. The path name is given in
29     unspecified case for basic identifiers and case-preserved for extended
30     identifiers.
31     FullName properties does not apply to libraryDecl class
32     Note: a local port or generic does not have a fullName.
33     Issue: do subpdecl and subpbody have fullName
34 p string -FullCaseName
35     Case preserved full name
36     FullCaseNameP property does not apply to libraryDecl class.
37     note: a local component port or generic does not have a full name
38 p string -FileName
39     pathname of the source file where that declaration
40     appears
41 p int -LineNo
42     line number where the declared identifier for the declared item appears in the
43     source
44 p int -LineOffset
45     The character offset in the source file of the definition name of the
46     declaration
47 p bool -IsImplicitDecl
48     Returns true for implicit constant, signals, functions
49     and procedure declarations.
50     For example:
51     this property returns true for GUARD signals of
52     blocks, for loop parameter and generate parameter, for implicit functions such
53     as OPEN, NEW, ...
54
55 one-to-one relationships:
56     mult 0..1 region<-lmmRegion vhpDecls returns all declarations of class vhpDecl in the

```

```

1 instance
2 vhpilmmRegion for a local ports/generics should
3 return null as the component declaration is not a
4 region.
5     mult 0..1 lexicalScope<-lexicalScope The lexical scope of a library declaration should return
6 null. For all other declarations, it should return the immediate scope where the delcaration is defi
7 ned.

33
34 Description:
35 an analyzed library unit (primary or secondary unit)
36
37 Superclasses: entityDesignator, lexicalScope
38
39 {
40     primaryUnit
41     secondaryUnit
42 }
43
44 Attributes:
45 p string  -LibLogicalName
46     the library logical name where that design unit can be found
47 p string  -LibPhysicalName
48     the physical name of the library where that design unit has been compiled
49 p int     -StartLineNo
50     the line number in the source where that library unit starts (includes the
51 line number of the library
52 and use clauses)
53 p int     -EndLineNo
54     the line number in the source where that described library unit ends
55 p string  -FileName
56     pathName of the source filename where that library unit was described

```

```

1  p string  -UnitName
2      name of the declared design unit in the VHDL source
3      name is unspecified case for basic identifiers or case-preserved for extended
4      identifiers The unitName of a design unit of the following class is:
5      EntityDecl: lib_name.entity_name
6      Arch body: lib_name.entity_name:arch_name
7      PackDecl: lib_name.pack_name
8      Pack Body: lib_name.pack_name:BODY
9      Config:    lib_name.config_name
10 p string  -Name
11     The identifier name of the declared design unit
12 p protectKindT  -ProtectedLevel
13     the level of protection of that design unit, 0 for complete visibility, 1 for
14     interface cell visibility (ports, generics, cell name, ...), 2 ...
15
16 p string  -CaseName
17
18 Iteration relationships:
19 it mult * spec<-spec The specifications defined in the design unit
20 For an archBody, there could be attrSpecs, disconnections or config specs)
21 for an entity or package declaration , it could be attribute or disconnection specs.
22 For a configDecl the specifications defined in the
23 configuration declarative part (only attribute specifications)
24 For a packBody, no specifications at all
25 it mult * pragma<-pragma internal
26 it mult 1..* designUnit<-DepUnits returns the dependent design units
27 it mult * decl<-Uses returns the declarations imported by a use clause that are referenced by the
28 design unit
29 it mult * decl<-decl the declarations (all kinds of the vhpDecl class) within the library unit not
30 including the
31 design unit itself
32 -----

48 Class driver
49
50 Superclasses: contributor
51
52 Attributes:
53 p int  -State
54     the driver state for the current simulation cycle: active, or disconnected, or
55     quiet, undefined.
56     Can be queried any time during a delta cycle before or after the driver

```

```

1    transaction matures.
2    This is an advanced property
3    p bool -IsPLI
4    is this a PLI created driver?
5    p int -Size
6    driver size in bytes?
7    p accessT -Access
8    read, write or no access at all to the driver
9
10   one-to-one relationships:
11       mult 1 eqProcessStmt<-eqProcessStmt
12       mult 1 basicSignal<-basicSignal returns the drivers for the basic signal.
13   note: a signal attribute is not a basic signal therefore you cannot iterate on drivers from a signal
14   attribute. VHPI should generate an error.
15   Iteration relationships:
16   it mult * transaction<-transaction
17   Operations:
18   -vhpi_schedule_transaction(drvhdl: vhpiHandleT, value: vhpiValueT *, delay: vhpiTimeT *,
19   delayMode: int, pulseRej: vhpiTimeT *, flags: int) : vhpiHandleT
20   -vhpi_get_value(handle: vhpiHandle, value: vhpi_value_p) : int
21       returns the current value of the driver
22   -vhpi_create(kind: int, basicSignal: vhpiHandle, process: vhpiHandle) : vhpiHandle
23   -vhpi_register_cb(cbdatap: vhpiCbDataT *, int flags: <unnamed>) : vhpiHandleT;
24
25   -----
26
27   Class driverCollection
28
29   Description:
30   A collection of driver handles.
31   All drivers must belong to the same signal and the same process.
32
33   Superclasses: uniformCollection, base
34
35   Operations:
36   -vhpi_schedule_transaction(hdl: vhpiHandle, values: vhpiValueT *, delay: vhpiTimeT, pulserej:
37   vhpiTimeT, flags: int) : vhpiHandle
38       The value is scheduled on the drivers of the collection. The value is
39       interpreted with respect to the order of the drivers in the collection.

1  stmt
2  name
3  literal
4  othersLiteral
5  allLiteral
6  }
7
8  Attributes:
9  p vhpiEntityClassT -EntityClass
10 the entity class enumeration values can be:
11 vhpi[Entity,Architecture, Configuration,Procedure,
12 Function,Package,Type,Subtype,Constant,Signal,Variable,Literal,Units,File,
13 Group, Component, Label]EC
14 If the entity designator is the others or all literal, the entity class will
15 be the entity class of the entities denoted by others or all. In case of an
16 entity designator for a disconnection specification, the entityClass is
17 vhpiSignalEC.
18 For name class, property returns the class of the name
19 as defined by the LRM page 71 A name entity class
20 can either be a procedure, signal, variable, group, function, variable,
21 literal, file, constant.
22 For unlabelled statements, return vhpiUndefined.
23

15     }
16
17     -----
18
19     Class fileDecl
20
21     Superclasses: objDecl, file
22
23     Attributes:
24     p openModeT -OpenMode
25     For VHDL 93:
26     -> In instantiated mode, the open mode of the file declaration either
27     WRITE_MORE, READ_MODE, APPEND_MODE.
28     -> In uninstantiated mode the open mode property may return vhpiUndefined (if
29     not open mode is specified or if the open mode expression is not a locally
30     static expression).
31
32     In VHDL 87, in instantiated access,
33     the OPEN_MODE is either vhpiInMode or vhpiOutMode.
34     in vhd 87, in uninstantiated access the vhpiOpenModeP property may return
35     vhpiInMode or vhpiOutMode. The default mode if the open mode is unspecified is
36     vhpiInMode.
37     p string -LogicalName
38     The file logical name if opened, or null if not opened.
39
40     one-to-one relationships:
41     mult 0..1 expr<-LogicalExpr Returns the expression providing the logical name of the file
42     declaration if the open information is provided

21 mult 0..1 derefObj<-DerefObj
22 Iteration relationships:
23 it mult * selectedName<-selectedName
24 it mult * indexedName<-indexedName
25 Operations:
26 -vhpi_put_value(handle: vhpiHandleT, value: vhpiValueT *, flags: vhpiPutValueModeT) : int
27 Mandatory for foreign function call, will set the return value of the foreign
28 function call,
29 legitimate vendor extension for VHDL function, not specified by the standard
30 If the function return type is a composite type which is not an array of
31 scalars, then individual vhpi_put_value class must be made to set each of the
32 sub-elements.
33

```

```

1 -----
2
3 Class portDecl
4
5 Description:
6 The following methods/properties are not allowed on a local port:
7
8
9 Superclasses: basicSignal, port, interfaceDecl
10
11 Attributes:
12 p sigKindT -SigKind
13   vhpBus or vhpNormal
14 p bool -IsGuarded
15 p bool -IsOpen
16 p modeT -Mode
17   mode is either vhpIn, vhpOut, vhpInOut, vhpBuffer or vhpLinkage
18   only signal/port class can be buffer or linkage mode.
19   A buffer signal can only have one source
20 p bool -IsLocal
21   true if this a local component port
22
23 one-to-one relationships:
24   mult 0..1 funcDecl<-ResolFunc returns a handle to the resolution function if if a resolution
25   function is associated with the declaration of that port or in the declaration of the port of that
26   signal (page 27 VHDL lrm 1076-93)
27
28 Iteration relationships:
29 it mult * selectedName<-selectedName
30 it mult * predefAttrName<-SigAttrs returns the signal attributes which are referenced in the VHDL
31 source or which have been created some other way (gui or vhp_create function)
32 it mult * indexedName<-indexedName
33 it mult * basicSignal<-basicSignal
34 Operations:
35 -vhp_put_value(handle: vhpHandleT; value: vhpValueT *; flags: vhpPutValueModeT) : int
36 -vhp_register_cb(cbdatap: vhpCbDataT *, int flags: <unnamed>) : vhpHandleT;
37
38 -----
39
40 internal Class pragma
41
42 Superclasses: base
43
44 Attributes:
45 p string -Name
46   the pragma name
47   ex "translate_on", "resolution_method" etc... as it appears in the VHDL
48   source
49 p string -StrVal
50   returns the pragma string value or null if no
51   string is supplied after the pragma name.
52   For example a pragma value string would be null for
53   "translate_on", or would be the entity name, or port name following the
54   pragmas "map_to_entity" or "return_port_name"
55   Pragmas which have a value string are pragmas of resolution function,built in
56   functions or subprograms.

10 mult 1 protectedTypeBody<-protectedTypeBody
11 -----
12
13 Class range
14
15 Description:
16 a range either integer, float range or a predefined attribute denoting a range
17 ('range or 'reverse_range attributes)
18
19 Superclasses: base, constraint
20
21 {
22   intRange
23   floatRange
24   physRange
25   enumRange
26 }
27
28 Attributes:
29 p bool -IsDiscrete
30 p bool -IsUp
31 p bool -IsNull
32   it is a null range
33 p bool -IsUnconstrained
34   true if range is unconstrained, false otherwise
35 p int -Staticness
36   returns vhpilLocallyStatic, vhpilGloballyStatic, or vhpilDynamic
37
38 one-to-one relationships:
39 mult 0..1 expr<-LeftExpr returns the leftExpr or NULL if range is unconstrained
40 also generates an error if range is unconstrained
41 mult 0..1 expr<-RightExpr return the right expression of the range or null if range
42 is unconstrained; generates an error if range is unconstrained
43 -----
44
45 Class realLiteral
46
47 Superclasses: abstractLiteral
48

24     name
25 }
26
27 -----
28
29 Class region
30
31 Description:
32 Class representing a VHDL scope in an elaborated model
33 A component instance statement that is unbound is still considered as
34 a scope. A for generate for which the range is NULL or an if generate for which
35 the condition is false is not considered as a scope
36
37 Superclasses: base, reference, reference
38
39 {
40     designInstUnit
41     generateStmt
42     blockStmt
43     protectedType
44     subpCall
45     eqProcessStmt
46     loopStmt
47 }
48
49 Attributes:
50 p string -FullName
51     full hierarchical statically instantiated name of the scope.
52     A for loop stmt is a dynamically elaborated region which has no fullname.
53     A sequential subprogram call is not a region and has no fullname.
54     A concurrent subprogram call is a region and has a fullname.
55     A function call is an expression and has no full name.
56     The name is returned in unspecified case characters unless it applies to names

```

1 of extended identifiers for which the case is preserved.
 2 It is the absolute path to the scope containing
 3 instance name (but no binding information as defined
 4 in the `instanceName` VHDL attribute)
 5 This property can only apply to objects living in a VHDL scope.
 6
 7 It starts by a ":" which denotes the top of the hierarchy followed by all the
 8 different scope instances to that scope. Each scope is separated by a ":".
 9 A scope name is either:
 10 a package body name,
 11 an instance name (instance label, generate index),
 12 a concurrent statement implicit or explicit label..
 13 p string -FullCaseName
 14 Full hierarchical instantiated case sensitive name of the region. Same
 15 restrictions as for `vhpiFullNameP`.
 16 The case is the case of the identifier declaring the region.
 17 p string -Name
 18 simple name of the static region instance
 19 A for loop stmt is a dynamically elaborated region and has no name. A
 20 sequential subprogram call is not a region and has no name. a concurrent
 21 procedure call
 22 is a region and has a name: the explicit or implicit label name. a function
 23 call is an expression and has no name.
 24 This is the name (unspecified case) for basic region identifiers or the
 25 case-preserved name for extended identifiers.
 26 This name is:
 27 for a component instance, the instance label name (ex. u1)
 28 for a generate instance, the generate label name with the index (ex. g(1))
 29 for a block instance, the block instance label (ex. b_lab)
 30 for a process instance, a created process label name (ex: _P<num> or _p<num>
 31 where num is an integer corresponding to the sequence number of the equivalent
 32 process appearing in the VHDL text source. num starts at 0 and increments by
 33 1. Numbering of unlabelled equivalent processes starts at the entity.
 34 for a rootInst: :
 35 for a package instance, the package body name
 36 (ex: pack1)
 37 for a subprogram call instance, the subprogram declaration name (ex: fp)
 38 p string -CaseName
 39 The case sensitive name of the declared region. Same as the `vhpiNameP` for
 40 extended identifiers or unlabelled eqprocesses. Same restrictions as for
 41 `vhpiNameP`.
 42 p string -DefName
 43 name which identifies the path to the declared thing
 44 in the library that is bound to this scope.
 45 For a `designInstUnit`, it is the
 46 lib_name:entity_name(arch_name),
 47 for a subprogram, it is:
 48 lib_name:entity_name(arch_name):subprogram_name
 49 if the subprogram is declared in an architecture
 50 lib_name:pack_body_name:subprogram_name
 51 if the subprogram body is declared in a package body
 52 for a processInst it is:
 53 lib_name:entity_name(arch_name):eq_process_label_name
 54 Each of the names is either unspecified for basic
 55 identifiers or case-preserved for extended identifiers.
 56 For unlabelled processes , it is the name generated by the VHPI interface

```

1  "_P<int>" or "_p<int>".
2
3  p string -FileName
4      pathname of the source file where that scope instance was found during
5      analysis
6  p int -LineNo
7      line number where the scope instance starts:
8      for a subpCall, the line number of the subprogram call,
9      for a rootInst, the line number of the definition of the architecture body it
10     is bound to,
11     for a packInst, the line number of the package body
12     for a complnst, the line number of the component instance,
13     for a generate instance, the line number of the generate statement,
14     for a block instance, the line number where the block statement starts in the
15     source
16     for a eqProcessStmt, the line number of the equivalent process statement.
17     For all kinds of regions, the line number should be the line number for that
18     region.
19  p int -LineOffset
20      The character offset in the source file of the definition
21      name of the scope (architecture name or package body name)
22  p : domainT #Domain
23      returns whether or not the region is digital, analog or mixed (vhpiDigital,
24      vhpiAnalog or vhpiMixedSignal)
25
26  one-to-one relationships:
27      mult 1 region<-UpperRegion Internal regions return the elaborated regions including:
28      - equivalent processes,
29      - structural concurrent statements.
30      - dynamically elaborated regions (for loop stmts and
31      subpCall).
32  However support of dynamically elaborated regions is not included in the compliance level of
33  hierarchy traversal.
34
35  UpperRegion: returns the higher enclosing structural instance or NULL if the reference handle is
36  a rootinst or a packinst.
37  Iteration relationships:
38  it mult * stmt<-stmt
39  it mult * region<-InternalRegions Internal regions return the elaborated regions including:
40  - equivalent processes,
41  - structural concurrent statements.
42  - dynamically elaborated regions (for loop stmts and
43  subpCall).
44  However support of dynamically elaborated regions is not included in the compliance level of
45  hierarchy traversal.
46
47  UpperRegion: returns the higher enclosing structural instance or NULL if the reference handle is
48  a rootinst or a packinst.
49  it mult * objDecl<-objDecl internal
50  it mult * decl<-decl vhpiDecls returns all declarations of clas vhpiDecl in the
51  instance
52  vhpiImmRegion for a local ports/generics should
53  return null as the component declaration is not a
54  region.
55  it mult * attrSpec<-attrSpec the attribute specifications attributing that region
56  (not the ones defined within that region)

```

46
47 one-to-one relationships:
48   mult 0..1 sigDecl<-GuardSig If the signal assign statement is guarded by a guard signal, then
49   returns the explicit or implicit guard signal declaration, otherwise returns null
50   mult 1 expr<-LhsExpr
51   mult 0..1 expr<-RejectTime
52 -----
53
54 Class sigDecl
55
56 Description:

```

```

1  a signal declaration
2
3  Superclasses: objDecl, basicSignal, signal
4
5  Attributes:
6  p bool -IsGuarded
7    the signal declares a guard signal of the signal kind indicated in the
8    declaration
9  p sigKindT -SigKind
10    signal kind register, bus or normal for signals,
11    bus or normal for ports.
12
13  one-to-one relationships:
14    mult 0..1 funcDecl<-ResolFunc returns the resolution function handle if a resolution function is
15    used to calculate the effective value of that signal: A resolution function handle will be returned if
16    the signal declaration contains a resolution function or of the subtype declaration of that signal
17    contains a resolution function.
18    mult 0..1 expr<-InitExpr
19  Iteration relationships:
20  it mult * selectedName<-selectedName

23   The string value of the literal as it appears in the VHDL
24
25 -----
26
27 Class subpBody
28
29 Description:
30 A subprogram body with its subprogram specification
31
32 Superclasses: reference, decl, lexicalScope
33
34 Attributes:
35 p bool  -IsForeign
36 p int   -BeginLineNo
37   the line number of the begin keyword
38 p int   -EndLineNo
39   the line number of the end keyword
40
41 one-to-one relationships:
42 mult 1 subpDecl<-subpDecl returns the subprogram specification of the subprogram body
43 Iteration relationships:
44 it mult * stmt<-stmt returns explicit sequential statements from the subpDecl
45 it mult * spec<-spec returns the specification defined in the subprogram declaration (only
46 Attribute specifications)
47 it mult * decl<-decl returns explicit declarations from the subpDecl
48 it mult * attrSpec<-attrSpec Returns the attribute specifications for that subprogram declaration
49 -----
50
51 Class subpCall
52
53 Superclasses: reference, region, stackFrame
54
55 {
56   funcCall

```

```

1  procCallStmt
2  }
3
4  Attributes:

6
7  one-to-one relationships:
8      mult 1 subpBody<-subpBody
9      mult 1 stackFrame<-CurStackFrame returns the current executing or suspended stack frame
10 or null.
11      mult 0..1 stackFrame<-UpStack moving up and down stack frames,
12 vhpiDownStack returns null if no more stack frame
13 vhpiUpStack returns null if this no more stack frame
14 Iteration relationships:
15 it mult * varDecl<-varDecl
16 it mult * paramDecl<-paramDecl iteration over the dynamically elaborated formals
17 (instantiated data) different from the paramDecl obtained
18 from a subpDecl handle
19 it mult * constDecl<-constDecl
20 it mult * assocElem<-ParamAssocs iteration over the parameter association as they appear
21 in the VHDL source it is not an ordered iteration
22 Operations:
23 -vhpi_handle_by_index(itRel: vhpiOneToManyT, handle: vhpiHandleT, index: int) : vhpiHandleT
24
25 -----
26
27 Class subpDecl
28
29 Description:
30 The subprogram declaration either found alone as a declaration or
31 as the subprogram specification of a subprogram body.
32
33 Superclasses: decl, lexicalScope
34
35 {
36   funcDecl
37   procDecl
38 }
39
40 Attributes:
41 p int -NumParams
42   the number of formal parameters in the subprogram
43   declaration includes the return parameter for
44   function declarations
45
46 one-to-one relationships:
47   mult 1 subpBody<-subpBody internal
48 Iteration relationships:
49 it mult * typeMark<-typeMark The signature of the subprogram either implicit or explicit
50 it mult * paramDecl<-paramDecl
51 it mult * paramDecl<-paramDecl iteration over uninstantiated parameter declarations
52 Operations:
53 -vhpi_handle_by_index(itRel: vhpiOneToManyT, handle: vhpiHandleT, index: int) : vhpiHandleT
54   returns the handle which corresponds to the index
55   for the given iteration for the reference handle
56

```

```

21 -----
22
23 Class subtypeDecl
24
25 Description:
26 a subtype declaration
27
28 Superclasses: decl, typeMark
29
30 Attributes:
31 p bool #IsResolved
32
33 one-to-one relationships:
34     mult 1 typeMark<-typeMark
35     mult 0..1 funcDecl<-ResolFunc returns a resolution function handle only if a resolution function
36 is present in the subtype declaration.
37 Iteration relationships:
38 it mult * constraint<-constraint
39 it mult * attrSpec<-attrSpec
40 -----
41
42 Class subtypeIndic
43
44 Superclasses: subtype, constraint
45
46 Attributes:
47 p bool #IsResolved
48     if the subtype indication has a resolution function associated with it.
49
50 one-to-one relationships:
51     mult 1 typeMark<-typeMark
52     mult 0..1 funcDecl<-ResolFunc returns a resolution function handle only if a resolution function
53 is present in the subtype indication
54 Iteration relationships:
55 it mult * constraint<-constraint
56 -----

```

```

1
2 Class tool
3
4 Description:
5 This represents the tool with which the VHPI application or models are
6 interacting; such a tool is an elaborator or a simulator which provides the VHPI
7 interface.
8
9 Superclasses: base
10
11 Attributes:
12 p string -Name
13   The tool vendor name: executable name which
14   implements the VHPI interface.
15 p int -Level
16   the VHDL conformance level:
17   0 : no VHPI support available
18   1: VHPI level 1
19   2: VHPI level 2
20   3: advanced VHPI capabilities
21 p int -VHDLversion
22   The language VHDL version the tool is complaint with: 87, 93 or 99
23 p physT -SimTimeUnit
24   The simulator tool time unit
25 p physT -Precision
26   The simulator precision for representing TIME values.
27 p PhaseT -Phase
28   the phase : vhpiRegistrationPhase, vhpiAnalysisPhase, vhpiInitializationPhase,
29   vhpiElaborationPhase vhpiSimulationPhase,
30   vhpiTerminationPhase, vhpiSavePhase, vhpiRestartPhase, vhpiResetPhase
31 p string -ToolVersion
32   The tool release version number
33
34 Iteration relationships:
35 it mult * argv<-argv Iteration returns the argv[] command line arguments passed to the tool
36 invocation in the order they were passed.
37 -----
38
39 Class transaction
40
41 Superclasses: base
42
43 Attributes:
44 p bool -IsNull
45
46 Operations:
47 -vhpi_get_value(handle: vhpiHandle, value: vhpi_value_p) : int
48 -vhpi_get_time(handle: vhpiHandle, time: vhpi_time_p) : bool
49
50 -----
51
52 Class typeConv
53
54 Superclasses: primaryExpr
55
56 one-to-one relationships:

```

```

1      mult 1 expr<-expr returns the expression that is the object of the conversion
2      -----
3
4      Class typeDecl
5
6      Superclasses: typeMark, decl
7
8      {
9      fileTypeDecl
10     scalarTypeDecl
11     compositeTypeDecl
12     accessTypeDecl
13     protectedTypeDecl
14     }
15
16     Attributes:
17     p bool #IsScalar
18     p bool #IsComposite
19
20     Iteration relationships:
21     it mult * attrSpec<-attrSpec
22     -----
23
24     Class typeMark
25
26     Description:
27     A type mark name that originated from a subtype declaration or type declaration
28
29     Superclasses: subtype
30
31     {
32     typeDecl
33     subtypeDecl
34     }
35
36     -----
37
38     Class unaryExpr
39
40     Superclasses: expr
41
42     one-to-one relationships:
43     mult 1 operator
44     <-operator
45
46     mult 1 expr<-expr
47     -----
48
49     Class uniformCollection
50
51     Description:
52     an homogeneous collection of handles. All handles gathered in this collection
53     are of the same kind, or a collection of handles of this
54     kind.
55
56

```

```

1  Superclasses: collection
2
3  {
4    driverCollection
5  }
6
7  -----
8
9  Class unitDecl
10
11 Description:
12 a unit declaration
13
14 Superclasses: decl
15
16 Attributes:
17 p phys -PhysPosition
18   the position number of this unit
19
20 one-to-one relationships:
21   mult 1 physLiteral<-physLiteral
22 -----
23
24 Class userAttrName
25
26 Superclasses: attrName
27
28 one-to-one relationships:
29   mult 1 attrSpec<-attrSpec returns the attribute specification which defines the value
30   of the userAttrName.
31 -----
32
33 Class varAssignStmt
34
35 Superclasses: seqStmt
36
37 one-to-one relationships:
38   mult 1 expr<-LhsExpr
39   mult 1 expr<-RhsExpr
40 -----
41
42 Class varDecl
43
44 Description:
45 a variable declaration
46
47 Superclasses: objDecl, variable
48
49 Attributes:
50 p bool -IsShared
51 p bool -IsProtectedType
52   The variable has a protected type
53
54 one-to-one relationships:
55   mult 0..1 expr<-InitExpr
56   mult 1 derefObj<-DerefObj method only from a variable of an access type

```

```

1  Iteration relationships:
2  it mult * selectedName<-selectedName
3  it mult * indexedName<-indexedName
4  Operations:
5  -vhpi_put_value(handle: vhpiHandleT, value: vhpiValueT *, flags: vhpiPutValueModeT) : int
6  -vhpi_protected_call(varHdl: vhpiHandleT, userfct: vhpiUserFctT, user_data: void *)
7  -vhpi_register_cb(cbdatap: vhpiCbDataT *, int flags: <unnamed>) : vhpiHandleT;
8
9  -----
10
11  Class varParamDecl
12
13  Superclasses: paramDecl, variable
14
15  Attributes:
16  p modeT -Mode
17    mode can be vhpiIn, vhpiOut, vhpiInOut
18
19  Operations:
20  -vhpi_put_value(handle: vhpiHandle, value: vhpi_value_p, flags: vhpiPutValueModeT) : int
21
22  -----
23
24  Class variable
25
26  Superclasses: interfaceElt
27
28  {
29    varDecl
30    varParamDecl
31    selectedName
32    indexedName
33  }
34
35  Attributes:
36  p bool -IsForced
37    true if the object has been externally forced by either
38    vhpi_put_value or some other way.
39    false otherwise
40
41  Iteration relationships:
42  it mult * callback<-callback
43  -----
44
45  Class waitStmt
46
47  Superclasses: seqStmt
48
49  one-to-one relationships:
50    mult 0..1 expr<-CondExpr
51    mult 0..1 expr<-TimeOutExpr
52  Iteration relationships:
53  it mult * name<-SigNames
54  -----
55
56  Class waveformElem

```

```

1
2 Superclasses: base
3
4 Attributes:
5 p bool -IsUnaffected
6 true if the waveforms is the unaffected keyword.
7 if true then valExpr and timeExpr methods return null;
8 always false for sequential signal assignments
9
10 one-to-one relationships:
11     mult 0..1 expr<-TimeExpr
12     mult 0..1 expr<-ValExpr
13 -----
14
15 Class whileLoop
16
17 Superclasses: iterScheme
18
19 one-to-one relationships:
20     mult 1 expr<-CondExpr
21 -----

```
