

Using the XC9500XL Timing Model

XAPP111 January 22, 1999 (Version 1.2)

Application Note

Summary

This application note describes how to use the XC9500XL timing model.

Xilinx Family

XC9500XL

Introduction

All XC9500XL CPLDs have a uniform architecture and an identical timing model, making them very easy to use and understand. To determine specific timing details, users need only compare their paths of interest to the architectural diagrams and, using the timing model presented here, perform a simple addition of incremental time delays.

Device Timing Overview

External signals arrive at the pins and are delivered through the I/O block to the FastCONNECT II Switch Matrix. From the switch matrix, they are dispatched to the various Function Blocks (FBs). As the signals enter the FBs, they incur incremental time delays depending on how the signals are used within the FB. For example, all logic signals must pass through the AND array where they encounter product terms which add a time delay as the signals progress. Additional time delay may be encountered if the signals pass through the cascade logic and are redirected toward macrocells that are farther away than those directly attached to the product terms.

There are additional timing requirements such as setup and clock-to-output times involved with passing signals through a flip-flop. As the signals exit flip-flops, they either pass to the outside world, through the I/O pins, or are fed back into the FastCONNECT II switch matrix for additional logic operations.

Design timing can be manually analyzed as separate signals, each having unique timing parameters that are easily calculated. However, the Xilinx software provides a detailed timing report that tallies and summarizes all paths specified by the designer. The timing report is based on the model described here and is a convenient text based mechanism for isolating and displaying timing relationships.

The timing model shown in Figure 1 is used by the M1 release of the Xilinx XACTstep development software which provides complete fitters for the XC9500XL family as well as the timing models for simulation and detailed static timing reports.

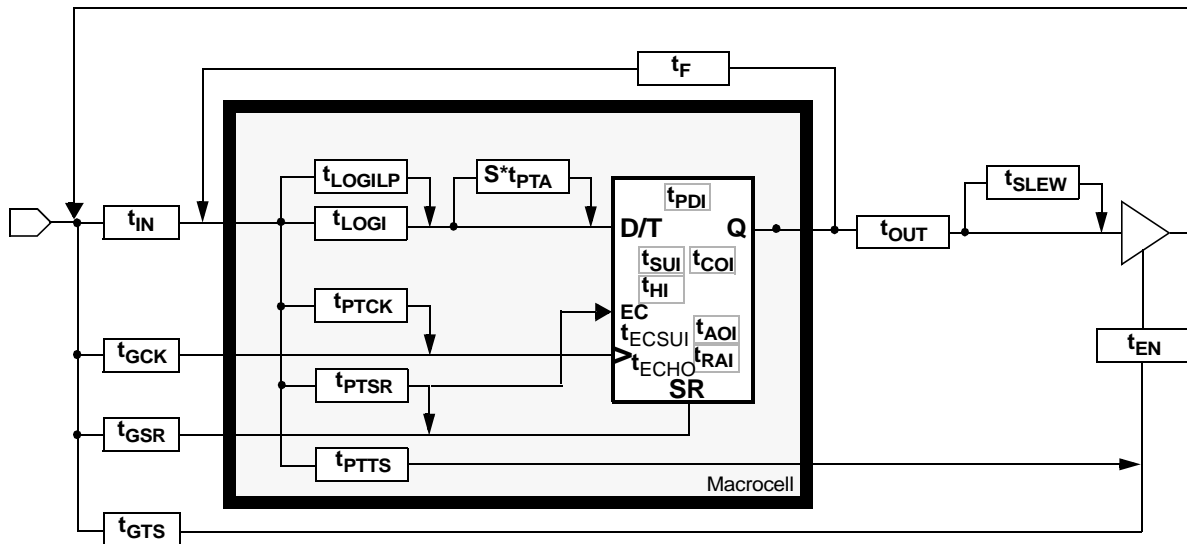

Figure 1: XC9500XL Detailed Timing Model

## Timing Model

The timing model shown in [Figure 1](#) resembles the XC9500XL macrocell with additional time delays included to account for the FastCONNECT II Switch Matrix and I/O buffers. As signals progress through an XC9500XL device, they encounter each of these delays which are tallied to arrive at a cumulative time delay for that signal. [Table 1](#) provides a detailed definition of each parameter contained in [Figure 1](#). The exact values of these parameters for each device can be obtained from the specific data sheets.

**Table 1: Key XC9500 Internal Timing Parameter Definitions**

| Symbol  | Parameter                                 |
|---|---|
| <b>Buffer Delays</b>                              |   |
| $t_{IN}$  | Input buffer delay                        |
| $t_{GCK}$   | GCK buffer delay                          |
| $t_{GSR}$   | GSR buffer delay                          |
| $t_{GTS}$   | GTS buffer delay                          |
| $t_{OUT}$   | Output buffer delay                       |
| $t_{EN}$  | Output buffer enable/disable delay        |
| <b>Product Term Control Delays</b>                |   |
| $t_{PTCK}$  | Product term clock delay                  |
| $t_{PTSR}$  | Product term set/reset/clock-enable delay |
| $t_{PTTS}$  | Product term 3-state delay                |
| <b>Internal Register and Combinatorial Delays</b> |   |
| $t_{PDI}$   | Combinatorial logic propagation delay     |
| $t_{SUI}$   | Register setup time                       |
| $t_{HI}$  | Register hold time                        |
| $t_{COI}$   | Register clock to output valid time       |
| $t_{AOI}$   | Register async. S/R to output delay       |
| $t_{RAI}$   | Register async. S/R recovery before clock |
| $t_{LOGI}$  | Internal logic delay                      |
| $t_{LOGILP}$                                      | Internal low power logic delay            |
| $t_{ECSUI}$                                       | Register Setup for Clock Enable           |
| $t_{ECHO}$  | Register Hold for Clock Enable            |
| <b>Feedback Delays</b>                            |   |
| $t_F$   | FastCONNECT II matrix feedback delay      |
| <b>Time Adders</b>                                |   |
| $t_{PTA}$   | Incremental product term allocator delay  |
| $t_{SLEW}$  | Slew rate limited delay                   |

## Timing Calculation Examples

[Table 2](#) shows how various external timing parameters are derived from the internal timing parameters. For example,  $t_{PD}$  is the sum of the input buffer time delay ( $t_{IN}$ ), the logic time delay ( $t_{LOGI}$ ), the flip-flop pass through delay ( $t_{PDI}$ ), and the output buffer time delay ( $t_{OUT}$ ), as shown in [Figure 2](#). Note that the input buffer delay is combined with the time delay accrued when the entering signal passes through the FastCONNECT II switch matrix.

**Figure 2: Simple  $t_{PD}$  Example**

**Table 2: Expressions for Key Timing Parameters Derived from [Table 1](#)**

| Symbol                 | Parameter                            | Calculation                                       |
|------------------------|--------------------------------------|---|
| $t_{PD}$               | Propagation delay*                   | $t_{IN} + t_{LOGI} + t_{PDI} + t_{OUT}$           |
| $t_{SU}$               | Global clock setup time*             | $t_{IN} + t_{LOGI} + t_{SUI} - t_{GCK}$           |
| $t_H$                  | I/O hold time after GCK              | $t_{GCK} + t_{HI} - t_{IN} - t_{LOGI}$            |
| $t_{CO}$               | Global clock-to-output*              | $t_{GCK} + t_{COI} + t_{OUT}$                     |
| $f_{SYSTEM}$           | Internal system clock period*        | $1/(t_{COI} + t_F + t_{LOGI} + t_{SUI})$          |
| $t_{PSU}$              | P-term Clock setup time*             | $t_{IN} + t_{LOGI} + t_{SUI} - t_{IN} - t_{PTCK}$ |
| $t_{PH}$               | I/O hold time after p-term clock     | $t_{IN} + t_{PTCK} + t_{HI} - t_{IN} - t_{LOGI}$  |
| $t_{PCO}$              | Product term clock-to-output         | $t_{IN} + t_{PTCK} + t_{COI} + t_{OUT}$           |
| $t_{ECSU}$             | Clock enable setup time              | $t_{IN} + t_{PTSR} + t_{ECSUI} - t_{GCK}$         |
| $t_{ECH}$              | Clock enable hold time               | $t_{GCK} + t_{ECHO} - t_{IN} - t_{PTSR}$          |
| $t_{OE}$<br>$t_{OD}$   | GTS to output enabled/disabled       | $t_{GTS} + t_{EN}$                                |
| $t_{POE}$<br>$t_{POD}$ | P-term OE to output enabled/disabled | $t_{IN} + t_{PTTS} + t_{EN}$                      |

Figure 3 shows a variation on the simple  $t_{PD}$  example with the addition of cascaded product terms. The time delay from input A is slightly altered by the addition of one  $t_{PTA}$  value which accounts for the additional product terms. The XC9500XL can accept and deliver product terms in both directions with the same  $t_{PTA}$  delay. Also, product terms may arrive from non-adjacent macrocells, which would require an additional  $t_{PTA}$  to be added for each macrocell hop. The design implementation software may incur multiple cascade delays as required to fit the design. This cascade timing can be managed by using timing driven optimization in Xilinx' CPLD software.

Figure 3:  $t_{PD}$  with Cascaded P-Terms

Figure 4 shows the results of supplementing single pass logic with an additional pass through another macrocell. In this case, there is a single pass through the input and output buffers, two passes through the macrocell logic, and a single pass through the feedback path.

Figure 4:  $t_{PD}$  with Multiple Pass Logic

Figure 5 shows the situation for a simple flip-flop clocked by a global clock signal (GCK). The expressions for  $t_{CO}$ ,  $t_H$ , and  $t_{SU}$  in Table 2 are valid for this arrangement.

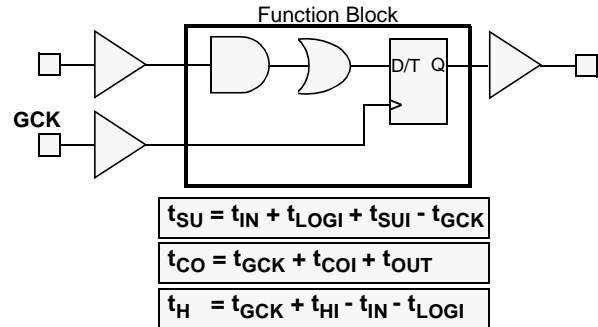

Figure 5: Simple Flip-Flop Path

(Note: EC not shown.)

Figure 6 shows the addition of another layer of macrocell logic into the situation described in Figure 5. The  $t_{CO}$  and  $t_H$  expressions remain the same, but the  $t_{SU}$  expression is increased by another  $t_{LOGI} + t_{PDI} + t_F$ .

5

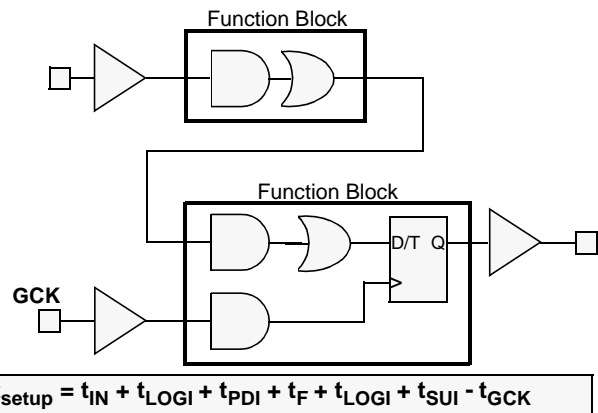

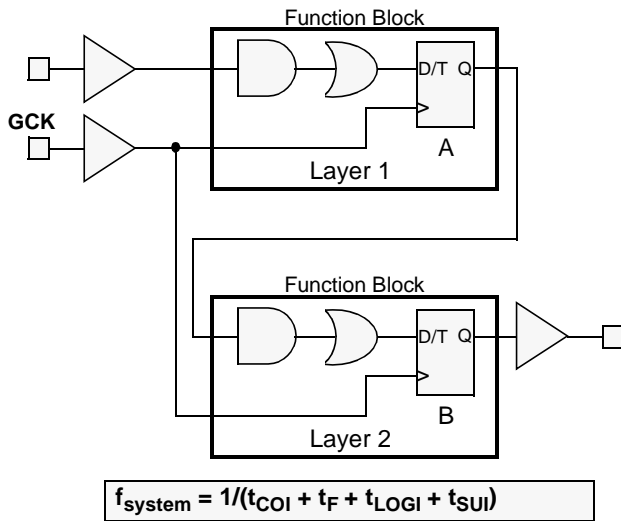

Figure 6: Flip-Flop with Two-Pass Logic

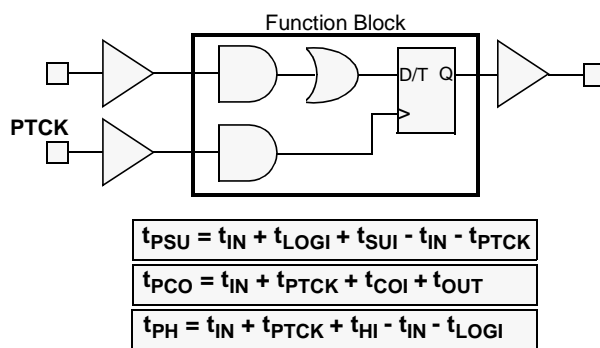

(Note: Global clock,  $t_{CO}$  and  $t_H$  are unchanged; EC not shown.)

Figure 7 shows two flip-flops connected by a single level of logic, clocked by a global clock. The  $t_{SU}$  and  $t_H$  for flip-flop A are identical to that of Figure 5.

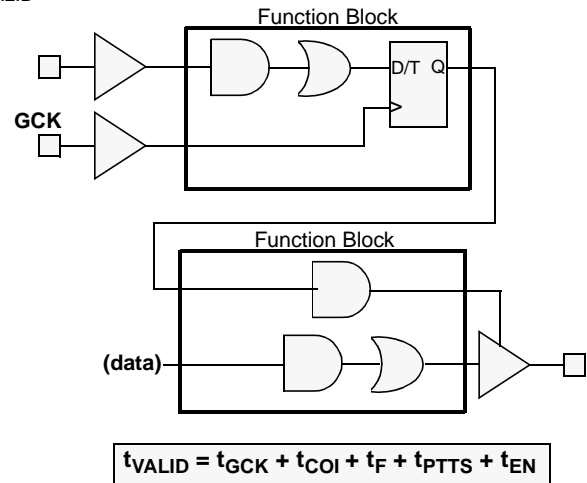

**Figure 7: Multiple Flip-Flops with Single Level Logic**  
(Note: EC not shown.)

Figure 8 shows a single flip-flop with a product term clock. This arrangement differs from Figure 5 only in that the clock input comes from a product term clock. The entry for  $t_{PCO}$  in Table 2 reflects this variation. The timing for  $t_{PSU}$  and  $t_{PH}$  is calculated using the product term clock timing parameters.

**Figure 8: Single Flip-Flop with Product Term Clock**  
(Note: EC not shown.)

Figure 9 shows the timing for driving valid data onto a bus with respect to a rising clock edge, a common configuration that occurs in high speed buses. This is sometimes called  $t_{VALID}$ .

**Figure 9: Flip-Flop-Controlled Output Enable**

(Note: EC not shown.)

Figure 5 through Figure 9 do not use the flip-flop clock enable.

Clock Enable (EC) is basically logic inserted before the flip-flop D input. Thus, EC has both setup ( $t_{ECSUI}$ ) and hold ( $t_{ECHO}$ ) time requirements.

Figure 10 shows how EC, which is driven by a product term, impacts  $f_{MAX}$ . Any additional feedback delays are added to the  $t_{setup}$  and/or  $f_{clock}$  calculations, which may impact system clock frequency.

**Figure 10: Flip-flop with Clock Enable**

(Note: Product term allocator delays ( $t_{PTA}$ ) and low power logic delays ( $t_{LOGILP}$ ) do not apply to Clock Enable timing calculations.)

### Low Power Mode

The power consumption of each macrocell in a CPLD device is programmable. The standard (default) setting consumes more power and produces shorter propagation delay. The low-power setting reduces power consumption for less speed-critical paths.

When a macrocell is operating in low power mode, substitute the delay term  $t_{\text{LOGILP}}$  in all timing calculations where  $t_{\text{LOGI}}$  normally appears.

### Conclusion

This set of examples is sufficient to describe a large number of design configurations, and other examples can easily be derived from the timing model. For manual calculations, other timing delays such as  $t_{\text{SLEW}}$  and  $t_{\text{LOGILP}}$  are easily added to the overall timing as required.
