Features

- Utilizes the AVR® RISC Architecture
- AVR – High-performance and Low-power RISC Architecture
  - 121 Powerful Instructions – Most Single Clock Cycle Execution
  - 32 x 8 General Purpose Working Registers + Peripheral Control Registers
  - Up to 6 MIPS Throughput at 6 MHz
- Data and Nonvolatile Program Memory
  - 128K Bytes of In-System Programmable Flash
    Endurance: 1,000 Write/Erase Cycles
  - 4K Bytes Internal SRAM
  - 4K Bytes of In-System Programmable EEPROM
    Endurance: 100,000 Write/Erase Cycles
  - Programming Lock for Flash Program and EEPROM Data Security
  - SPI Interface for In-System Programming
- Peripheral Features
  - On-chip Analog Comparator
  - Programmable Watchdog Timer with On-chip Oscillator
  - Programmable Serial UART
  - Master/Slave SPI Serial Interface
  - Real Time Counter (RTC) with Separate Oscillator
  - Two 8-bit Timer/Counters with Separate Prescaler and PWM
  - Expanded 16-bit Timer/Counter System, with Separate Prescaler, Compare, Capture Modes and Dual 8-, 9-, or 10-bit PWM
  - Programmable Watchdog Timer with On-chip Oscillator
  - 8-channel, 10-bit ADC
- Special Microcontroller Features
  - Low-power Idle, Power Save and Power-down Modes
  - Software Selectable Clock Frequency
  - External and Internal Interrupt Sources
- Specifications
  - Low-power, High-speed CMOS Process Technology
  - Fully Static Operation
- Power Consumption at 4 MHz, 3V, 25°C
  - Active: 5.5 mA
  - Idle Mode: 1.6 mA
  - Power-down Mode: < 1 µA
- I/O and Packages
  - 32 Programmable I/O Lines, 8 Output Lines, 8 Input Lines
  - 64-lead TQFP
- Operating Voltages
  - 2.7 - 3.6V (ATmega103L)
  - 4.0 - 5.5V (ATmega103)
- Speed Grades
  - 0 - 4 MHz (ATmega103L)
  - 0 - 6 MHz (ATmega103)

Description

The ATmega103(L) is a low-power CMOS 8-bit microcontroller based on the AVR RISC architecture. By executing powerful instructions in a single clock cycle, the ATmega103(L) achieves throughputs approaching 1 MIPS per MHz allowing the system designer to optimize power consumption versus processing speed.

The AVR core is based on an enhanced RISC architecture that combines a rich instruction set with 32 general purpose working registers. All the 32 registers are directly connected to the Arithmetic Logic Unit (ALU), allowing two independent registers to be accessed in one single instruction executed in one clock cycle. The resulting architecture is more code efficient while achieving throughputs up to ten times faster than conventional CISC microcontrollers.

The ATmega103(L) provides the following features: 128K bytes of in-system programmable Flash, 4K bytes EEPROM, 4K bytes SRAM, 32 general purpose I/O lines, 8 input lines, 8 output lines, 32 general purpose working registers, real time counter (RTC), 4 flexible timer/counters with compare modes and PWM, UART, programmable watchdog timer with internal oscillator, an SPI serial port and three software selectable power saving modes. The Idle mode stops the CPU while allowing the SRAM, timer/counters, SPI port and interrupt system to continue functioning. The Power-down mode saves the register contents but freezes the oscillator, disabling all other chip functions until the next interrupt or hardware reset. In Power Save mode, the timer oscillator continues to run, allowing the user to maintain a timer base while the rest of the device is sleeping.

The device is manufactured using Atmel's high-density nonvolatile memory technology. The on-chip ISP Flash allows the program memory to be reprogrammed in-system through a serial interface or by a conventional nonvolatile memory programmer. By combining an 8-bit RISC CPU with a large array of ISP Flash on a monolithic chip, the Atmel ATmega103(L) is a powerful microcontroller that provides a highly flexible and cost-effective solution to many embedded control applications.

The ATmega103(L) AVR is supported with a full suite of program and system development tools including: C compilers, macro assemblers, program debugger/simulators, in-circuit emulators, and evaluation kits.

Pin Descriptions

VCC

Supply voltage

GND

Ground

Port A (PA7..PA0)

Port A is an 8-bit bi-directional I/O port. Port pins can provide internal pull-up resistors (selected for each bit). The Port A output buffers can sink 20 mA and can drive LED displays directly. When pins PA0 to PA7 are used as inputs and are externally pulled low, they will source current if the internal pull-up resistors are activated.

Port A serves as Multiplexed Address/Data bus when using external SRAM.

The port A pins are tri-stated when a reset condition becomes active, even if the clock is not running.

Port B (PB7..PB0)

Port B is an 8-bit bi-directional I/O port with internal pull-up resistors. The Port B output buffers can sink 20 mA. As inputs, Port B pins that are externally pulled low, will source current if the pull-up resistors are activated.

Port B also serves the functions of various special features.

The port B pins are tri-stated when a reset condition becomes active, even if the clock is not running.

Port C (PC7..PC0)

Port C is an 8-bit output port. The Port C output buffers can sink 20 mA.

Port C also serves as Address output when using external SRAM.

Since Port C is an output only port, the port C pins are **not** tri-stated when a reset condition becomes active.

Port D (PD7..PD0)

Port D is an 8-bit bi-directional I/O port with internal pull-up resistors. The Port D output buffers can sink 20 mA. As inputs, Port D pins that are externally pulled low will source current if the pull-up resistors are activated.

Port D also serves the functions of various special features.

The port D pins are tri-stated when a reset condition becomes active, even if the clock is not running.

Port E (PE7..PE0)

Port E is an 8-bit bi-directional I/O port with internal pull-up resistors. The Port E output buffers can sink 20 mA. As inputs, Port E pins that are externally pulled low will source current if the pull-up resistors are activated.

Port E also serves the functions of various special features.

The port E pins are tri-stated when a reset condition becomes active, even if the clock is not running

Port F (PF7..PF0)

Port F is an 8-bit input port. Port F also serves as the analog inputs for the ADC.

$\overline{\text{RESET}}$

Reset input. An external reset is generated by a low level on the $\overline{\text{RESET}}$ pin. Reset pulses longer than 50 ns will generate a reset, even if the clock is not running. Shorter pulses are not guaranteed to generate a reset.

XTAL1

Input to the inverting oscillator amplifier and input to the internal clock operating circuit.

XTAL2

Output from the inverting oscillator amplifier.

TOSC1

Input to the inverting Timer/Counter oscillator amplifier.

TOSC2

Output from the inverting Timer/Counter oscillator amplifier.

$\overline{WR}$

External SRAM write strobe

$\overline{RD}$

External SRAM read strobe

ALE

ALE is the Address Latch Enable used when the External Memory is enabled. The ALE strobe is used to latch the low-order address (8 bits) into an address latch during the first access cycle, and the AD0-7 pins are used for data during the second access cycle.

AVCC

Supply voltage for Port F, including ADC. The pin must be connected to VCC when not used for the ADC. See “ADC Noise Canceling Techniques” on page 71 for details when using the ADC.

AREF

This is the analog reference input for the ADC converter. For ADC operations, a voltage in the range AGND to AVCC must be applied to this pin.

AGND

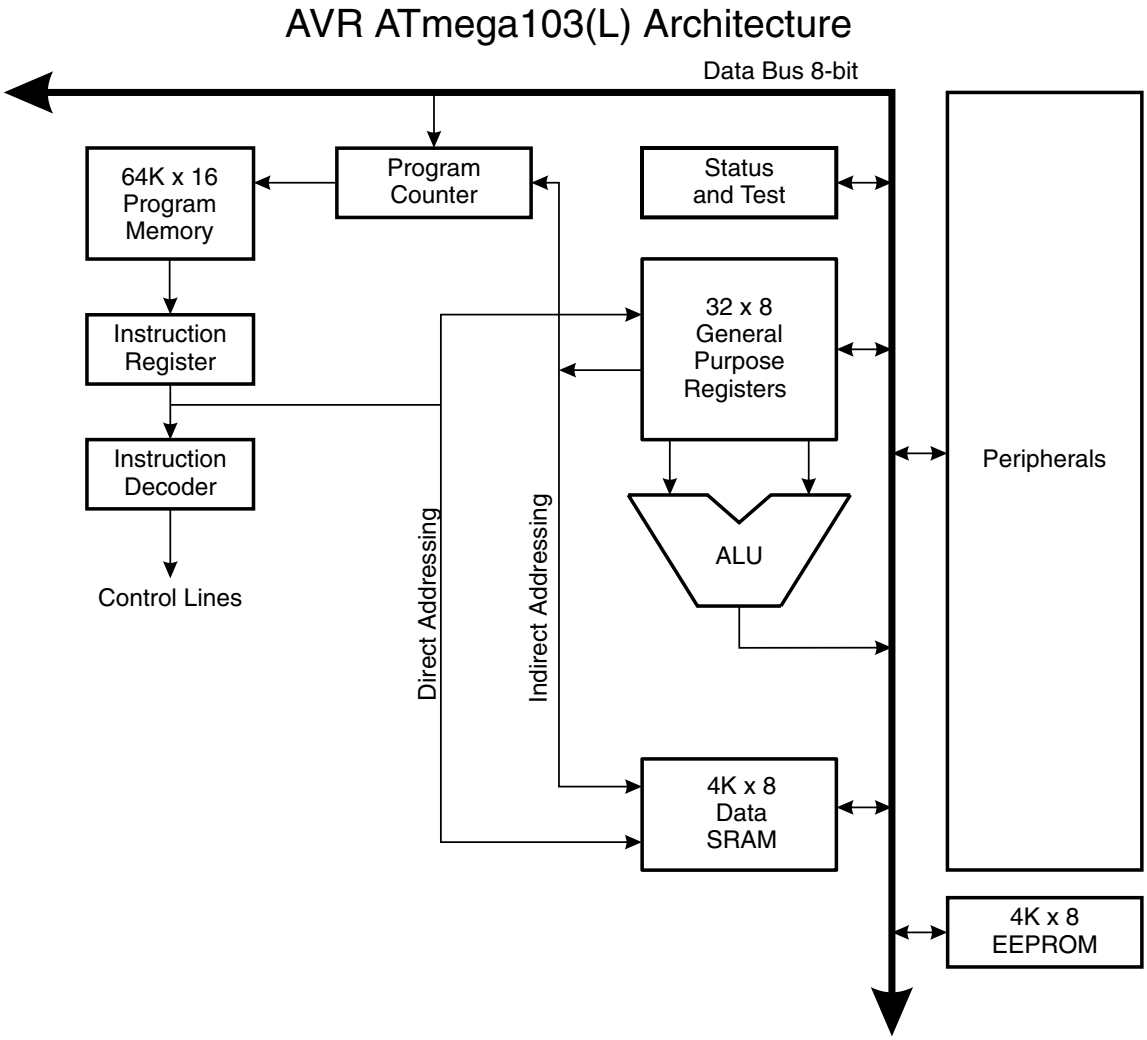
If the board has a separate analog ground plane, this pin should be connected to this ground plane. Otherwise, connect to GND.

$\overline{PEN}$

This is a programming enable pin for the serial programming mode. By holding this pin low during a power-on reset, the device will enter the serial programming mode. $\overline{PEN}$ has no function during normal operation.

Architectural Overview

Figure 2. The ATmega103(L) AVR RISC Architecture



The AVR uses a Harvard architecture concept – with separate memories and buses for program and data. The program memory is accesses with a single level pipeline. While one instruction is being executed, the next instruction is pre-fetched from the program memory. This concept enables instructions to be executed in every clock cycle. The program memory is in-system programmable Flash memory. With a few exceptions, AVR instructions have a single 16-bit word format, meaning that every program memory address contains a single 16-bit instruction.

During interrupts and subroutine calls, the return address program counter (PC) is stored on the stack. The stack is effectively allocated in the general data SRAM, and consequently the stack size is only limited by the total SRAM size and the usage of the SRAM. All user programs must initialize the SP in the reset routine (before subroutines or interrupts are executed). The 16-bit stack pointer SP is read/write accessible in the I/O space.

The 4000 bytes data SRAM can be easily accessed through the five different addressing modes supported in the AVR architecture.

Note: For compatibility with future devices, reserved bits should be written to zero if accessed. Reserved I/O memory addresses should never be written. Some of the status flags are cleared by writing a logical one to them. Note that the CBI and SBI instructions will operate on all bits in the I/O register, writing a one back into any flag read as set, thus clearing the flag. The CBI and SBI instructions work with registers $00 to $1F only.
