

## Definition of Terms

In this document, some specifications may be designated as Advance or Preliminary. These terms are defined as follows:

**Advance:** Initial estimates based on simulation and/or extrapolation from other speed grades, devices, or families. Values are subject to change. Use as estimates, not for production.

**Preliminary:** Based on preliminary characterization. Further changes are not expected.

**Unmarked:** Specifications not identified as either Advance or Preliminary are to be considered Final.

Except for pin-to-pin input and output parameters, the AC parameter delay specifications included in this document are derived from measuring internal test patterns. All limits are representative of worst-case supply voltage and junction temperature conditions. Typical numbers are based on measurements taken at a nominal  $V_{CCINT}$  level of 2.5V and a junction temperature of 25°C. The parameters included are common to popular designs and typical applications. **All specifications are subject to change without notice.**

#### Notes:

1. Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those listed under Operating Conditions is not implied. Exposure to Absolute Maximum Ratings conditions for extended periods of time may affect device reliability.
2. Power supplies may turn on in any order.
3.  $V_{IN}$  should not exceed  $V_{CCO}$  by more than 3.6V over extended periods of time (e.g., longer than a day).
4. Spartan-II I/Os are 5V Tolerant whenever the LVTTL, LVCMS2, or PCI33\_5 signal standard has been selected. With 5V Tolerant I/Os selected, the Maximum DC overshoot must be limited to either +5.5V or 10 mA, and undershoot must be limited to either -0.5V or 10 mA, whichever is easier to achieve. The Maximum AC conditions are as follows: The device pins may undershoot to -2.0V or overshoot to +7.0V, provided this over/undershoot lasts no more than 11 ns with a forcing current no greater than 100 mA.
5. Without 5V Tolerant I/Os selected, the Maximum DC overshoot must be limited to either  $V_{CCO} + 0.5$  V or 10 mA, and undershoot must be limited to -0.5V or 10 mA, whichever is easier to achieve. The Maximum AC conditions are as follows: The device pins may undershoot to -2.0V or overshoot to  $V_{CCO} + 2.0$  V, provided this over/undershoot lasts no more than 11 ns with a forcing current no greater than 100 mA.
6. For soldering guidelines, see the Packaging Information on the Xilinx website: [www.xilinx.com/partinfo/pkgs.htm](http://www.xilinx.com/partinfo/pkgs.htm)

- Minimum and maximum values for  $V_{CCO}$  vary according to the I/O standard selected.
- Input and output measurement threshold is ~50% of  $V_{CCO}$ .
- Supply voltages may be applied in any order desired.

**Notes:**

- With no output current loads, no active input pull-up resistors, all I/O pins 3-stated and floating.
- Internal pull-up and pull-down resistors guarantee valid logic levels at unconnected input pins. These pull-up and pull-down resistors do not provide valid logic levels when input pins are connected to other circuits.

## Supply Current Requirements During Power-On

Spartan-II FPGAs require that a minimum supply current  $I_{CCPO}$  be provided to the  $V_{CCINT}$  lines for a successful power-on. If more current is available, the FPGA can consume more than  $I_{CCPO}$  min., though this cannot adversely affect reliability.

A maximum limit for  $I_{CCPO}$  is not specified. Be careful when using foldback/crowbar supplies and fuses. It is possible to control the magnitude of  $I_{CCPO}$  by limiting the supply current available to the FPGA. A current limit below the trip level will avoid inadvertently activating over-current protection circuits.

Symbol	Description		Min <sup>(1)</sup>	Max	Units
$I_{CCPO}$	Total $V_{CCINT}$ supply current required during power-on	$0^{\circ}\text{C} \leq T_J \leq 100^{\circ}\text{C}$ <sup>(2)</sup>	500	-	mA
		$-40^{\circ}\text{C} \leq T_J < 0^{\circ}\text{C}$	2	-	A
$T_{CCPO}$	$V_{CCINT}$ ramp time <sup>(3,4)</sup>		-	50	ms

### Notes:

- The  $I_{CCPO}$  requirement applies for a brief time (commonly only a few milliseconds) when  $V_{CCINT}$  ramps from 0 to 2.5V.
- Applies to both Commercial and Industrial devices.
- The ramp time is measured from GND to  $V_{CCINT}$  max on a fully loaded board.
- $V_{CCINT}$  must not dip in the negative direction during power on.

## DC Input and Output Levels

Values for  $V_{IL}$  and  $V_{IH}$  are recommended input voltages. Values for  $V_{OL}$  and  $V_{OH}$  are guaranteed output voltages over the recommended operating conditions. Only selected standards are tested. These are chosen to ensure that all

standards meet their specifications. The selected standards are tested at minimum  $V_{CCO}$  with the respective  $I_{OL}$  and  $I_{OH}$  currents shown. Other standards are sample tested.

## Switching Characteristics

Testing of switching parameters is modeled after testing methods specified by MIL-M-38510/605. All devices are 100% functionally tested. Internal timing parameters are derived from measuring internal test patterns. Listed below are representative values. For more specific, more precise, and worst-case guaranteed data, use the values reported

by the static timing analyzer (TRCE in the Xilinx Development System) and back-annotated to the simulation netlist. All timing parameters assume worst-case operating conditions (supply voltage and junction temperature). Values apply to all Spartan-II devices unless otherwise noted.

### Notes:

1. Output timing is measured at 1.4V with 35 pF external capacitive load for LVTTL. For other I/O standards and different loads, see the tables **Constants for Calculating T<sub>loop</sub>** and **Delay Measurement Methodology, page 10**.

## Calculation of $T_{IOOP}$ as a Function of Capacitance

$T_{IOOP}$  is the propagation delay from the O Input of the IOB to the pad. The values for  $T_{IOOP}$  are based on the standard capacitive load ( $C_{SL}$ ) for each I/O standard as listed in the table **Constants for Calculating  $T_{IOOP}$** , below.

For other capacitive loads, use the formulas below to calculate an adjusted propagation delay,  $T_{IOOP1}$ .

$$T_{IOOP1} = T_{IOOP} + \text{Adj} + (C_{LOAD} - C_{SL}) * F_L$$

Where:

Adj is selected from **IOB Output Delay Adjustments for Different Standards**, page 9, according to the I/O standard used

$C_{LOAD}$  is the capacitive load for the design

$F_L$  is the capacitance scaling factor

## Clock Distribution Switching Characteristics

T<sub>GPIO</sub> is specified for LVTTL levels. For other standards, adjust T<sub>GPIO</sub> with the values shown in **I/O Standard Global Clock Input Adjustments**.

## DLL Timing Parameters

Switching parameters testing is modeled after testing methods specified by MIL-M-38510/605; all devices are 100 percent functionally tested. Because of the difficulty in directly measuring many internal timing parameters, those parame-

ters are derived from benchmark timing patterns. The following guidelines reflect worst-case values across the recommended operating conditions.

Symbol	Description	Speed Grade				Units	
		-6		-5			
		Min	Max	Min	Max		
$F_{CLKINHF}$	Input clock frequency (CLKDLLHF)	60	200	60	180	MHz	
$F_{CLKINLF}$	Input clock frequency (CLKDLL)	25	100	25	90	MHz	
$T_{DLLPWHF}$	Input clock pulse width (CLKDLLHF)	2.0	-	2.4	-	ns	
$T_{DLLPWLF}$	Input clock pulse width (CLKDLL)	2.5	-	3.0	-	ns	

## DLL Clock Tolerance, Jitter, and Phase Information

All DLL output jitter and phase specifications were determined through statistical measurement at the package pins using a clock mirror configuration and matched drivers.

$T_{PHOOM}$	Maximum phase difference between clock outputs on the DLL <sup>(5)</sup>		-	$\pm 200$	-	$\pm 200$	ps

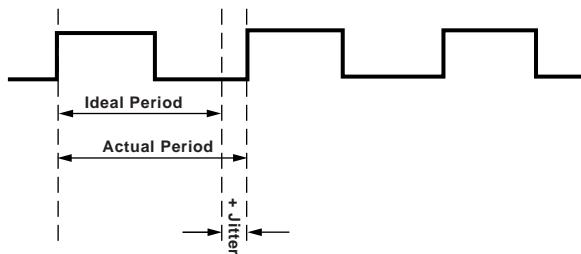

### Notes:

1. **Output Jitter** is cycle-to-cycle jitter measured on the DLL output clock, *excluding* input clock jitter.
2. **Phase Offset between CLKIN and CLKO** is the worst-case fixed time difference between rising edges of CLKIN and CLKO, *excluding* output jitter and input clock jitter.
3. **Phase Offset between Clock Outputs on the DLL** is the worst-case fixed time difference between rising edges of any two DLL outputs, *excluding* Output Jitter and input clock jitter.
4. **Maximum Phase Difference between CLKIN and CLKO** is the sum of Output Jitter and Phase Offset between CLKIN and CLKO, or the greatest difference between CLKIN and CLKO rising edges due to DLL alone (*excluding* input clock jitter).
5. **Maximum Phase Difference between Clock Outputs on the DLL** is the sum of Output Jitter and Phase Offset between any DLL clock outputs, or the greatest difference between any two DLL output rising edges due to DLL alone (*excluding* input clock jitter).

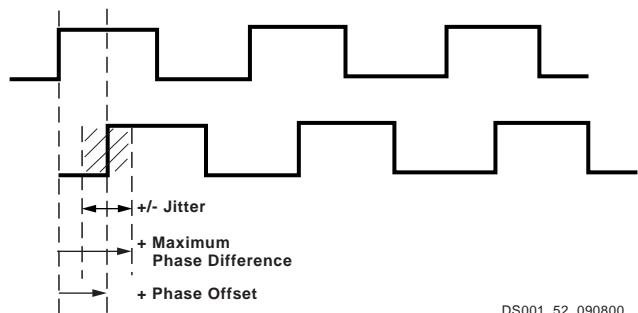

**Period Tolerance:** the allowed input clock period change in nanoseconds.

**Output Jitter:** the difference between an ideal reference clock edge and the actual design.
